# Multitopic 3,2':6', $3^{\prime \prime}$-terpyridine ligands as 4-connecting nodes in two-dimensional 4,4-networks $\dagger$ 

Giacomo Manfroni, (D) Bernhard Spingler, (D) Alessandro Prescimone, (D) ${ }^{\text {a }}$ Edwin C. Constable (1) ${ }^{\text {a }}$ and Catherine E. Housecroft (D)*a

#### Abstract

The tetratopic 1,4-bis(2-phenylethoxy)-2,5-bis(3, $2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-terpyridin-4'-yl)benzene (1) and 1,4-bis(3-phenylpropoxy)-2,5-bis(3,2':6', $3^{\prime \prime}$-terpyridin- $4^{\prime}$-yl)benzene (2) ligands have been prepared and fully characterised. Combination of ligand 1 or 2 and $\left[M(h f a c a c)_{2}\right] \cdot x H_{2} \mathrm{O}(M=C u, x=1 ; M=Z n, x=2)$ under conditions of crystal growth by layering led to the formation of $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot 3 \cdot 6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}-\right.$ $\left.\mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}, \quad\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}, \quad\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$, $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ and $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0 \cdot 4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$. For each compound, single-crystal X-ray analysis revealed the assembly of a planar $(4,4)$-net in which the tetratopic ligands 1 or 2 define the nodes. The metal centres link two different bis( $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy) ligands via the outer pyridine rings; whereas copper(॥) has N -donors in a trans-arrangement, zinc(॥) has them in cis. This difference between the copper(॥) and zinc(॥) coordination polymers modifies the architecture of the assembly without changing the underlying (4,4)-network.

## Introduction

The symmetric, divergent and isomeric ligands, $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$ terpyridine ( $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$-tpy) and $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-terpyridine ( $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$ tpy) are well-suited for use as building blocks in supramolecular chemistry, ${ }^{1}$ with their ability to participate in $\pi$-stacking and directional hydrogen-bonding interactions in addition to binding metal centres. Their 4'-aryl functionalized derivatives are readily prepared using the one-pot Hanan ${ }^{2}$ procedure, which is based on the general method of Kröhnke, ${ }^{3}$ although there are some serendipitous instances in which cyclic products are favoured. ${ }^{4}$ Unlike $2,2^{\prime}: 6^{\prime}, 2^{\prime \prime}$-tpy, which typically coordinates as a tridentate $\kappa^{3}$ chelating unit, the central pyridine ring is non-coordinating in $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy and $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$-tpy, and typically, they behave as ditopic $N, N^{\prime}$ donor ligands. These two tpy isomers possess different degrees of coordination flexibility (Scheme 1). In $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$-tpy,

[^0]inter-ring $\mathrm{C}-\mathrm{C}$ bond rotation does not affect the orientation of the $N, N^{\prime}$-donor set, leading to a V-shaped building block. In contrast, conformational changes (Scheme 1) determine the directionality of the $N, N^{\prime}$-donor set in $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy leading to a more versatile and less predictable network assembly. ${ }^{5}$

Although many examples of 1D-, 2D- and 3D-assemblies have been prepared from ligands containing one or more $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$-tpy units, the coordination behaviour of $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy ligands remains less exploited. ${ }^{1,5-25}$ We have reported three copper(II) 1D-coordination polymers

4,2':6', 4"-tpy

3,2:6', $3^{3 "-t p y ~}$

B

Scheme 1 Divergent binding mode of 4,2':6', $4^{\prime \prime}$-tpy, and some of the possible binding modes (labelled A-C) that $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy can adopt via inter-ring $\mathrm{C}-\mathrm{C}$ bond rotation. The two tpy isomers coordinate only through the outer N atoms.
$\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(\mathrm{~L} 1)_{2}\right]_{n} \cdot n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \quad($ Hhfacac $=1,1,1,5,5,5-$ hexafluoropentane-2,4-dione), $\quad\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(\mathrm{~L} 1)_{2}\right]_{n} \cdot n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$, and $\left[\mathrm{Cu}(\mathrm{hfacac})_{2}(\mathrm{~L} 2)\right]_{n} \cdot n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$, containing ditopic $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$ tpy ligands with coordinatively innocent $4^{\prime}$-substituents. In $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(\mathrm{~L} 1)_{2}\right]_{n} \cdot n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right)$ and $\left.\left[\mathrm{Cu}_{2} \text { (hfacac) }\right)_{4}(\mathrm{~L} 2)_{2}\right]_{n} \cdot n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ the $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy domains exhibit conformation $\mathbf{C}$, while with $\left[\mathrm{Cu}(\text { hfacac })_{2}(\mathrm{~L} 2)\right]_{n} \cdot n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ conformation $\mathbf{B}$ is adopted (Scheme 1). ${ }^{26}$ Structures of ligands L1 and L2 are shown in Scheme 2.

One strategy for increasing the dimensionality of an assembly is to select metal centres which favour higher coordination numbers combined with ditopic $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy or $4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}$-tpy linkers. The resulting coordination network is thereby directed by the metal node. ${ }^{5,27}$ An alternative methodology to encourage the formation of 2 D - and 3 D dimensional assemblies is by connecting multiple tpy domains to appropriate scaffolds. Two $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy or $4,2^{\prime}: 6^{\prime}, 4$ "-tpy units can be linked in a "back-to-back" fashion by any organic spacer, generating a tetratopic ligand. ${ }^{8,28}$ We decided to extend our investigations of [M(hfacac) $)_{2}$ ] coordination chemistry to tetratopic bis(tpy) ligands, and we recently demonstrated the assembly of a series of $(4,4)$ nets based on 1,4-bis(n-alkyloxy)-2,5-bis( $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-terpyridin-4'-yl) benzene ligands. ${ }^{29}$ A search of the Cambridge Structural Database (CSD v. 2021.3.0, April 2022) revealed only three other structures involving a $\operatorname{bis}\left(4,2^{\prime}: 6^{\prime}, 4^{\prime \prime}\right.$-tpy) or $\operatorname{bis}\left(3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}\right.$ tpy) with a metal 1,3-diketonate. Yoshida et al. showed that ligand L3 (Scheme 3) combined with [Co(acacCN) $)_{2}$ ] (HacacCN $=2$-acetyl-3-oxobutanenitrile) gives the 2D-dimensional $(4,4)$ net $\left[\mathrm{Co}_{2}(\operatorname{acacCN})_{4}(\mathrm{~L} 3)\right]_{n}$. The replacement of $\left[\mathrm{Co}(\operatorname{acacCN})_{2}\right]$ by $\left[\mathrm{Co}(\mathrm{dbm})_{2}\right](\mathrm{Hdbm}=1,3$-diphenylpropane-1,3-dione) leads to a 1D-chain $\left[\mathrm{Co}(\mathrm{dbm})_{2}(\mathrm{~L} 3)\right]_{n}$, in which L3 is bidentate through one pyridine $N$-donor from each tpy domain. The low connectivity is perhaps sterically induced by the presence of larger phenyl rings in $\left[\mathrm{Co}(\mathrm{dbm})_{2}\right]$. In contrast, in $\left[\mathrm{Co}_{2}(\operatorname{acacCN})_{4}(\mathrm{~L} 4)\right]_{n}$, a change in the ligand from L3 to L4 (Scheme 3) with $\left[\mathrm{Co}(\mathrm{dbm})_{2}\right.$ ] does not change the topology of the coordination network, but the networks exhibit 3-fold interpenetration in the solid state structure. ${ }^{25}$

In this work, we report the synthesis of two bis $\left(3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}\right.$ tpy) ligands 1 and 2 (Scheme 4) with 1,4-phenylene spacers containing 2-phenylethoxy and 3-phenylpropoxy substituents attached to the phenylene moiety. We have already demonstrated that introducing alkyloxy groups enhances the solubility of the ligand in organic solvents which is beneficial for crystal growth. In addition, the nature of the alkyloxy group can influence the assembly and if terminal phenyl

L3

L4

Scheme 3 Structures of the tetratopic bis(tpy) ligands L3 and L4.
groups are present, they may participate in $\pi-\pi$ stacking interactions within the solid state. ${ }^{5,8,28}$ Herein, we describe the reaction of 1 and 2 (potentially tetratopic ligands) with $\left[\mathrm{M}(\mathrm{hfacac})_{2}\right](\mathrm{M}=\mathrm{Cu}, \mathrm{Zn})$, a two connecting building block, to generate a series of 2-dimensional (4,4)-networks. The electron-withdrawing effect of the $\mathrm{CF}_{3}$ substituents improves the affinity of the complex towards coordination with the pyridine donors of the tetratopic ligands as well as improving its solubility in organic solvents.

## Experimental

Materials and full synthetic procedures are given in the ESI, $\dagger$ including characterization. Crystallographic data are given in Tables 1 and 2.

## Results and discussion

## Ligand synthesis and characterization

Compounds 1 and 2 were prepared using an established route for related bis(terpyridine) ligands (Scheme 4). ${ }^{30}$ Bouveault aldehyde syntheses ${ }^{31}$ starting from the reaction of 1,4-dibromo-2,5-bis(2-phenylethoxy)benzene or 1,4-dibromo-2,5-bis(3-phenylpropoxy)benzene with $n$-BuLi and DMF in dry $\mathrm{Et}_{2} \mathrm{O}$ at $0{ }^{\circ} \mathrm{C}$, gave 1a (59\%) and 2a (37\%), respectively. Despite the use of excess of $n$-BuLi and DMF, monoaldehyde by-products persisted and purification by column chromatography was required. Finally, Hanan and Wang's one-pot strategy, ${ }^{2}$ provided the desired terpyridines 1 (35\%)

Scheme 4 Synthetic route to 1 and 2. Reagents conditions (see ESI $\dagger$ for full details): (i) $n$ - $\mathrm{BuLi}^{2} \mathrm{Et}_{2} \mathrm{O}, \mathrm{O}^{\circ} \mathrm{C}$; dry DMF, warmed to room temperature, 22 h; (ii) 3-acetylpyridine, $\mathrm{KOH}, \mathrm{NH}_{3}, \mathrm{EtOH}, \mathrm{RT}, 6$ days for 1 and 5 days for 2.

and 2 (36\%) after filtration and washing with water, EtOH and $\mathrm{Et}_{2} \mathrm{O}$, and no further purification was needed.

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of intermediates $\mathbf{1 a} \mathbf{- 1 b}$ and 1-2 were assigned using NOESY, COSY, HMQC and HMBC techniques (Fig. S1-S12†). The spectroscopic signatures are consistent with the structures displayed in Scheme 4. Melting point determination, ATR-IR spectroscopies (Fig. S13-S16†), UV-vis (Fig. S17†) and MALDITOF mass spectrometry (Fig. S18-S21 $\dagger$ ) and either HR-ESI mass spectrometry (Fig. S22-S23†) or elemental analysis complemented the characterisation (see $\mathrm{ESI} \dagger$ for full details).

## Single crystal structures of 1 a and 2 a

Single crystals of 1a grew from the chromatographic fractions after purification (EtOAc in cyclohexane, 2-5\% gradient). X-ray quality crystals of 2 a were obtained as a hot EtOAc solution of 2 a was allowed to cool to $-20^{\circ} \mathrm{C}$. 1a crystallises in the monoclinic space group $P 2_{1} / n$ and $2 \mathbf{a}$ in the
orthorhombic Pbca space group. In both $1 \mathbf{a}$ and $2 \mathbf{a}$, the asymmetric unit contains one crystallographic independent half-molecule and the second half is generated by inversion with the inversion centre located in the arene core centroid. The conformations of $\mathbf{1 a}$ and $\mathbf{2 a}$ are slightly different (Fig. 1). The extension of the phenylalkoxy substituent by the addition of an additional $\mathrm{CH}_{2}$ has a considerable impact on the crystal packing.

Intermolecular interactions in the crystal lattice in 1a arise from a combination of $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, short C $\mathrm{H} \cdots \pi$ (arene) contacts, and arene-arene $\pi$-stacking. The $\mathrm{C}-$ $\mathrm{H} \cdots \mathrm{O}$ bonds arise from the oxygen atom of the aldehydes and the hydrogen atoms H5A and H5B attached to C5, with $\mathrm{C} \cdots \mathrm{O}$ distance of $3.12 \AA(\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ range of $2.65-2.95 \AA)$ and $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ angles range of $90.4-126.3^{\circ}$. Only one crystallographically independent $\pi$-stacking interaction occurs (Fig. 2a). The terminal phenyl ring containing C10 stacks with the neighbouring ring containing C10 ${ }^{\mathrm{ii}}$ across an inversion centre (symmetry code ii $=1-x, 1-y,-z$ ). The rings are offset with respect to each other and the centroid $\cdots$ centroid separation is $4.12 \AA$. The interactions are then supplemented by short $\mathrm{C}-\mathrm{H} \cdots \pi$ (arene) contacts.

In contrast, the packing in $2 \mathbf{a}$ is dominated by $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. Two CHO groups interact via a pair of $\mathrm{C}-$ $\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds, generating a six-membered ring through a centrosymmetric arrangement; hydrogen bond metrics are $\mathrm{C} 1^{\mathrm{ii}} \cdots \mathrm{O} 1=3.27 \AA\left(\mathrm{C} 1^{\mathrm{ii}}-\mathrm{H} 1^{\mathrm{ii}} \cdots \mathrm{O} 1=2.52 \AA\right), \mathrm{C} 1^{\mathrm{ii}}-$ $\mathrm{H} 1^{\mathrm{ii}} \cdots \mathrm{O} 1=135.9^{\circ}$ (symmetry code $\mathrm{ii}=-x,-y, 1-z$ ). The interconnection of the CHO groups arranges the molecules into 1D ribbons as shown in Fig. 2b. The individual ribbons are parallel with respect to each other and the stacking is slightly staggered following an ABAB pattern (Fig. $\mathrm{S} 24 \dagger$ ). Weak short $\mathrm{C}-\mathrm{H} \cdots \pi$ (arene) interactions link the different stacks.

The self-association of aromatic aldehydes dimers via C $\mathrm{H} \cdots \mathrm{O}$ interactions is rare. A search of the Cambridge Structural Database (CSD v. 2021.3.0, April 2022) for structures containing aromatic aldehydes reveals that only 157 out of 4039 crystal structures form dimers of the type found in 2a. Statistical analysis, using normalised $H$, reports mean distances of $2.57(10)$ and $2.58(9) \AA$ for the pair of C$\mathrm{H} \cdots \mathrm{O}$ interactions involved in dimer formation, with $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ angles of $130(14)$ and $129(14)^{\circ}$, respectively. In our case, a C$\mathrm{H}^{\cdots} \mathrm{O}$ distance of $2.42 \AA$ and an angle of $133.6^{\circ}$ (with normalised H ) are consistent.

## Crystal growth experiments

Solutions of $\left[\mathrm{M}(\text { hfacac })_{2}\right] \cdot x \mathrm{H}_{2} \mathrm{O}(\mathrm{M}=\mathrm{Cu}, x=1 ; \mathrm{M}=\mathrm{Zn}, x=2)$ in either toluene, chlorobenzene or 1,2-dichlorobenzene were layered over a chloroform solution of 1 or 2 at room temperature. The reactions were carried out using molar metal/ligand ratios of 2:1 (see ESI $\dagger$ for full details). For each ligand, X-ray quality crystals were obtained with different solvent combinations, leading to sets of crystals that led to the five crystal structures listed in Tables 2 and 3.
Table 2 Crystallographic data of the coordination polymers $\left[\mathrm{Cu}_{2}\left(\text { hfacac }^{2}(1)\right]_{n} \cdot 3 \cdot 6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3},\left[\mathrm{Zn}_{2}\left(\mathrm{hfacac}_{4}(1)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3},\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{HH}_{2} \mathrm{O},\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6}-\right.\right.$ $\mathrm{H}_{5} \mathrm{Cl}$ and $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0 \cdot 5 n \mathrm{H}_{2} \mathrm{O}$

(b)

Fig. 2 (a) Face-to-face $\pi$-stacking between two molecules of 1a. H atoms are omitted for clarity. (b) $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonding between molecules of 2 a leads to ribbons.

Structural analysis confirmed the assembly of a 2Dcoordination polymer in each case, comprising solvated coordination networks with the general formula $\left[\mathrm{M}_{2}(\mathrm{hfacac})_{4}(\mathrm{~L})\right]_{n}(\mathrm{M}=\mathrm{Cu}, \mathrm{Zn})$. From the reaction between 2 and $\left[\mathrm{Cu}(\mathrm{hfacac})_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$, single crystals grew from three solvent combinations yielding $\quad\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$
(from toluene/ $\mathrm{CHCl}_{3}$ ), $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ (from chlorobenzene $\left./ \mathrm{CHCl}_{3}\right)$ and $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}-\right.$ $\mathrm{H}_{4}$ ) $\cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ (from 1,2-dichlorobenzene/ $\mathrm{CHCl}_{3}$ ). The first two are isostructural networks which crystallise in the triclinic space group $P \overline{1}$ and possess comparable cell dimensions ( $a=8.9300(2), b=15.7218(3), c=16.4219(3) \AA$ A,$\alpha$ $=100.0302(15), \beta=93.7146(16), \gamma=96.8981(18)^{\circ}$ for $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$, and $a=8.9544(2), b=$ 15.7417(4), $c=16.3905(4) \AA, \alpha=100.053(2), \beta=94.071(2), \gamma=$ $97.071(2)^{\circ}$ for $\left.\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}\right)$. Therefore, we only discuss in detail the structure of $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$. In $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2}-\right.$ $\left.\mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$, a change in conformation of the $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy domains justifies a separate description of this structure. All five assemblies are (4,4)-nets, but two structurally distinct designs can be identified and are discussed separately: (4,4)-nets with a trans-arrangement of the $\left\{\mathrm{Cu}(\mathrm{hfacac})_{2}\left(\mathrm{~N}_{1}\right)\left(\mathrm{N}_{2}\right)\right\}$ units and a (4,4)-net with cis-arrangement of the $\left\{\mathrm{Zn}(\text { hfacac })_{2}\left(\mathrm{~N}_{1}\right)\left(\mathrm{N}_{2}\right)\right\}$ units (Scheme 5).

## (4,4)-Networks containing $\mathrm{Cu}(\text { hfacac })_{2}$

$\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(\mathbf{1})\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$ crystallises in the monoclinic space group $P 2_{1} / n$, while $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ and $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n(1,2-$ $\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \cdot \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ crystallise in the triclinic space group $P \overline{1}$. In $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$ the asymmetric unit contains one independent copper atom and one independent half-ligand (Fig. $\mathrm{S} 25 \dagger$ ). In contrast, the asymmetric units of $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ and $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ contain two independent half copper atoms and one independent half-ligand (Fig. S26-S27 $\dagger$ ). The copper centres lie on crystallographic inversion centres. For $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}, \mathrm{Cu} 2$ is disordered over an inversion centre (Fig. $\mathrm{S} 27 \dagger$ ); for the discussion of the polymer, only the mean position is considered. In all three compounds, each $\mathrm{Cu}(\mathrm{II})$ centre is octahedrally coordinated with a trans-arrangement of coordinated [hfacac] ${ }^{-}$ligands. Bond lengths and angles in the $\mathrm{Cu}(\mathrm{II})$ coordination sphere are typical, with $\mathrm{Cu}-\mathrm{N}$ distances in the range $1.981(5)-2.048(9) \AA$ and $\mathrm{Cu}-\mathrm{O}$ in the range $1.979(4)-2.330(5) \AA$. In both coordinated ligand 1 and 2, the two tpy domains are crystallographically related, with the phenylene spacer centroid lying on an inversion centre. Each bis(tpy) ligand binds through the outer nitrogen donors to

Table 3 Crystal structures and the experimental solvent for $\left[\mathrm{Cu}(\mathrm{hfacac})_{2}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Zn}(\mathrm{hfacac})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, and space groups. The solvent for ligands 1 and 2 was $\mathrm{CHCl}_{3}$

Scheme 5 Schematic representations of (a) trans-\{Cu(hfacac) $\left(N_{1}\right)$ $\left.\left(\mathrm{N}_{2}\right)\right\}$ and (b) cis-\{Zn(hfacac) $\left.)_{2}\left(\mathrm{~N}_{1}\right)\left(\mathrm{N}_{2}\right)\right\}$ fragments. $\mathrm{N}_{1}$ and $\mathrm{N}_{2}$ originate from two different bis(tpy) ligands.

(a)

(b)
four $\mathrm{Cu}($ II) centers, therefore acting as the 4 -connecting node and directing the assembly of a $(4,4)$-net. The tpy units are non-planar and the torsion angles between the ring planes range between $4.5^{\circ}$ and $33.6^{\circ}$ (Table 4). Torsion angles of $34.5^{\circ}, 39.1^{\circ}$ and $51.1^{\circ}$ between the planes of the central pyridine ring and the central arene spacer are typical for minimising $\mathrm{H} \cdots \mathrm{H}$ inter-ring repulsions.

In $\quad\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot 3 \cdot 6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3} \quad$ and $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ both ligand $\mathbf{1}$ and 2 adopt conformation $\mathbf{B}$. Interestingly, with ligand 2 , a solvent change from chlorobenzene (or toluene) to 1,2-dichlorobenzene leads to a conformational change of the tpy groups within the 2 D polymer (Fig. 3 b and c , top). In fact, in $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$, ligand 2 displays conformation $\mathbf{C}$, although this does not lead to a significant change in the network (Fig. 3b and c, middle). In all three structures, the combination of ligand 1 or 2 with $\mathrm{Cu}(\text { hfacac })_{2}$ leads to a 2D-net directed by the tetratopic ligands. The centroids of the phenylene spacers are the nodes of the network, whereas the copper centres act as linkers (Fig. 3, middle). The network in $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot 3.6 n(1,2-$ $\left.\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$ contains a rhombic shortest circuit with internal angles of 87.0 and $93.0^{\circ}$ and a node $\cdots$ node distance of $16.94 \AA$. The copper atoms are close to the plane of the (4,4)-net generating a small deformation in the structure (Fig. 3a, middle and bottom). In contrast, in $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ and $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n(1,2-$ $\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4} \cdot \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$, the shortest circuits are parallelograms (Fig. 3b and c, middle) with the copper centres lying in the plane (Fig. 3b and c, bottom). The conformational change of ligand 2 does not appear to play a crucial role in the assembly. Indeed, from $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ to $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2}-\right.$ $\left.\mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$, only minor changes occur in the distances and angles between the individual nodes (Table 5).

All the structures considered in this section have phenylalkoxy groups pointing above and below the plane
(Fig. 3, bottom). $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(\mathbf{1})\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$ and $\quad\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ were crystallised in the same solvent mixture (from 1,2-dichlorobenzene/ $\mathrm{CHCl}_{3}$ ) and with the same reagent concentrations. The only difference is in the length of the phenylalkoxy substituent, ligand 1 possesses a 2-phenylethoxy whereas ligand 2 possesses a 3-phenylpropoxy. Despite the difference of only one $\mathrm{CH}_{2}$ group, the network is significantly affected going from $\quad\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}-\right.$ $\left.\mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3} \quad$ to $\quad\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}-\right.$ $\mathrm{H}_{4}$ ). $0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ (Fig. 3a and c). It is important to note that, in $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$, the peripheral phenyl ring is not involved in any significant interaction, whereas in $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}-\right.$ $\left.\mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$, short $\mathrm{C}-\mathrm{H} \cdots \pi$ (arene) interactions link the pendant phenyl ring with the 1,2-dichlorobenzene molecule and the phenylene spacer of the ligand in the adjacent sheet (Fig. S28 $\dagger$ ). The 3-phenylpropoxy substituent also engages in weak interactions in the crystal structure of $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$, where the terminal phenyl ring stacks with the central arene spacer of the ligand 2 contained in a neighbouring (4,4)-net (Fig. S29 $\dagger$ ). In each lattice, the individual layers pack with the cavities running down the crystallographic $a$-axis (Fig. 4). The solvent molecules are accommodated within these open channels.

## (4,4)-Network containing Zn (hfacac) $\mathbf{2}_{2}$

Single crystals of $\left[\mathrm{Zn}_{2}(\text { hfacac })_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$ were grown by layering a toluene solution of $\left[\mathrm{Zn}(\mathrm{hfacac})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ over a $\mathrm{CHCl}_{3}$ solution of 1. $\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6}-$ $\mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$ crystallises in the monoclinic space group $P 2_{1} /$ $n$. The asymmetric unit contains one independent Zn (II) centre and one independent half-ligand; the second half is generated by inversion (Fig. S30 $\dagger$ ). The Zn atom is octahedrally sited and coordinated to four oxygen atoms of two chelating [hfacac] ligands ( $\mathrm{Zn}-\mathrm{O}$ in the range 2.083(2)$2.136(2) \AA$ ), and to two pyridine donor atoms of two different ligands $1(\mathrm{Zn}-\mathrm{N}=2.100(1), 2.120(3) \AA)$, which are in a cis-arrangement. The coordination sphere is distorted with an $\mathrm{N}-\mathrm{Zn}-\mathrm{N}$ bond angle of $97.70(10)^{\circ}$ and similar values have been reported previously for cis-\{Zn(hfacac) $\left.)_{2}\left(\mathrm{~N}_{1}\right)\left(\mathrm{N}_{2}\right)\right\}$ complexes with substituted pyridine donors. ${ }^{33-35}$ The tpy domain adopts conformation $\mathbf{C}$ (Scheme 1) and the angles between the planes of the rings containing $\mathrm{N} 1 / \mathrm{N} 2$ and $\mathrm{N} 2 / \mathrm{N} 3$ are 25.2 and $3.9^{\circ}$, respectively. The phenylene spacer is rotated $50.7^{\circ}$ relative to the pyridine ring containing N2. Note

Table 4 Angles between the planes of pairs of connected rings in the coordinated ligands

(b)

(c)

Fig. 3 Comparison of the ligand conformations and the (4,4) nets in (a) [ $\left.\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot 3 \cdot 6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$, (b) $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$, and (c) $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$. Top, conformation of the coordinated ligand; middle, looking down on the sheets; bottom, $(4,4)$ nets observed through the mean plane determined by the nodes of the ligand centroids (green). For clarity, H atoms, coordinated [hfacac] ligands and solvent are omitted, and only major occupancies are shown.

Table 5 Distances and angles between the nodes in the (4,4)-nets

| Compound | Node-node distance/ $\AA$ | Internal angles of rhombus in $(4,4)$ net/ ${ }^{\circ}$ |
| :--- | :--- | :--- |
| $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$ | 16.94 | $87.0,93.0$ |
| $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ | $16.42,17.12$ | $78.8,101.2$ |
| $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$ | $16.17,20.68$ | $73.0,107.0$ |

that when the metal is not on an inversion centre and the two $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy units are in conformation $\mathbf{C}$ (Scheme 1), three spatial arrangements of tpy domains are possible (Scheme 6). In $\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$, pairs of ligand 1 are arranged in the orientation III as shown in Scheme 6.

As with the complexes described in the previous section, ligand 1 behaves as a 4-connecting node, coordinating four different $\mathrm{Zn}(\mathrm{II})$ ions and directing the assembly of a planar (4,4)-net (Fig. 5a). The distance between adjacent ligand nodes (centroids of the phenylene spacers) is $15.11 \AA$ and the internal angles of the rhombic shortest circuit are 59.4 and $120.6^{\circ}$. Compared to the copper(II) structures reported in this work, the topology of the zinc(II) network is identical. However, structural differences can be seen by examination of how the metal linkers and the phenylalkoxy tails are arranged. The zinc(II) centres are disposed alternately above
and beneath the plane generated by the ligand nodes, while the 2-phenylethoxy chains are located in the plane (Fig. 5b). Each cavity of the network accommodates two 2-phenylethoxy tails, both originating from the same individual 2Dcoordination polymer, and the pendant phenyl rings interact via face-to-face $\pi$-interaction across an inversion centre (Fig. S31†).

Note that a change from a trans to a cis arrangement of the N -donors on going from the $\mathrm{Cu}(\mathrm{II})$ to $\mathrm{Zn}(\mathrm{II})$ structures modifies the architecture of the assembly without changing the underlying (4,4)-network. On the other hand, we have recently reported a planar (4,4)-net with trans- $\left\{\mathrm{Cu}(\mathrm{hfacac})_{2}\left(\mathrm{~N}_{1}\right)\left(\mathrm{N}_{2}\right)\right\}$ domains lying above and below the plane displaying a similar arrangement of metal linkers. ${ }^{29}$ In $\left[\mathrm{Zn}_{2}(\text { hfacac })_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$, viewed down the crystallographic $b$-axis, the individual layers are parallel to each other (Fig. S32 $\dagger$ ). The packing of the sheets

Fig. 4 (a) Illustration of the void space in the crystal lattices of $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ (ca. $21 \%$ void) with channels following the a-axis. (b) Representation of the same structure with solvent molecules. The void was calculated from the structure without solvent molecules. Subsequently, the same structure with solvent molecules was superimposed on the one without, revealing the chlorobenzene in the channels. Contact surface map with probe radius $=1.2 \AA$. Calculations made with Mercury (v. 2021.3.0). ${ }^{32}$

Scheme 6 With pairs of $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy ligands in conformation C (Scheme 1), there are three possible coordination topology (I)-(III) at a Zn atom that does not lie on an inversion center. The labels in and out indicate the orientation of the lone pair of each coordinating N atom relative to the central N atom of the $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy unit. Only limiting planar conformations are shown and coordinated oxygen atoms arise from [hfacac] ${ }^{-}$ligands.
shows a zig-zag arrangement with the $\mathrm{CF}_{3}$ groups protruding out of the plane. Interactions between the layers are dominated by short $\mathrm{C}-\mathrm{H} \cdots \mathrm{F}-\mathrm{C}$ contacts between 2-phenylethoxy substituents in one sheet and the $\mathrm{CF}_{3}$ groups from the neighbouring one. However, since the $\mathrm{CF}_{3}$ groups

(a)

(b)

Fig. 5 Shortest circuit with four nodes (ligand centroids, green) of the $(4,4)$ net in $\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(1)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$; (a) looking down on the sheet, (b) $(4,4)$ net observed through the mean plane determined by the nodes. For clarity, H atoms, coordinated [hfacac] ligands and solvent are omitted, and only major occupancies are shown.
are disordered, a detailed discussion is not meaningful. Removal of the solvent molecules from the structure reveals cavities (Fig. 6) rather than open channels in which they are located.

## Bulk sample analysis

Once single crystals had been selected for single-crystal X-ray structure diffraction, the bulk materials were analysed by powder X-ray diffraction (PXRD). All the crystalline materials were sensitive to loss of solvent upon exposure to air and were thus measured wet and without washing them. For $\left.\left[\mathrm{Cu}_{2} \text { (hfacac) }\right)_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$, all peaks in the

Fig. 6 Illustration of the void space in the crystal lattices of $\left[\mathrm{Zn}_{2}(\text { hfacac })_{4}(1)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$ (ca. $33 \%$ void) following the a-axis. Contact surface map with probe radius = $1.2 \AA$. Calculations made with Mercury (v. 2021.3.0). ${ }^{32}$
experimental PXRD pattern (red traces in Fig. 7) correspond to the predicted pattern from the single crystal structure (black traces in Fig. 7). Preferred orientations of the crystallites explain the differences in the relative intensities of the peaks (blue traces in Fig. 7). In the same manner, for $\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$, a good match was found between the experimental PXRD pattern for the bulk material and the pattern predicted from the single-crystal structure (Fig. S33 $\dagger$ ). On the other hand, the fitting between the calculated and experimental patterns of the remaining compounds did not show a good match and are shown in Fig. S34-S36. $\dagger$ Unlike the single-crystal X-ray determinations, which were carried out at low temperatures, the PXRD patterns were recorded at room temperature. Phase transition and solvent loss can affect the PXRD significantly and in view of the observed facile solvent loss, we did not investigate the crystallographic properties of the bulk material further.

The solid state IR spectra of the dried copper(II) coordination polymers are shown in Fig. S37-S40. $\dagger$ Not surprisingly, given the similarity of the structures, the absorption of the 1,3 -diketonate and the fingerprint regions are almost identical.

Fig. 7 (a) X-ray diffraction ( $\mathrm{CuK} \alpha_{1}$ radiation) pattern (red circles) of the bulk crystalline material of $\left[\mathrm{Cu}_{2}(\text { (hfacac })_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$, fitting the predicted pattern from the single crystal structure. The black lines are the best fit from Rietveld refinements, and green lines display the Bragg peak positions. The blue plot gives the difference between calculated and experimental points. (b) Expansion in the $2-32^{\circ}$ range.

## Conclusions

We have synthesised and characterised two bis( $3,2^{\prime}: 6^{\prime}, 3^{\prime}-$ tpy $) \mathbf{1}$ and 2 ligands, featuring 2-phenylethoxy and 3-phenylpropoxy substituents attached to the 1,4 -phenylene spacer, respectively. Ligands 1 and 2 were then allowed to react with $\left[M(h f a c a c)_{2}\right] \cdot x \mathrm{H}_{2}$ $\mathrm{O}(\mathrm{M}=\mathrm{Cu}, x=1 ; \mathrm{M}=\mathrm{Zn}, x=2)$ under ambient condition of crystal growth in a combination of $\mathrm{CHCl}_{3}$ and an aromatic solvent. The single crystal determination revealed the formation of the 2 D -coordination networks $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot 3.6 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6}\right.$ $\left.\mathrm{H}_{4}\right) \cdot 2 n \mathrm{CHCl}_{3}$, $\quad\left[\mathrm{Zn}_{2}(\text { hfacac })_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$, $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}, \quad\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{Cl}$ and $\quad\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot 2 n\left(1,2-\mathrm{Cl}_{2} \mathrm{C}_{6} \mathrm{H}_{4}\right) \cdot 0.4 n \mathrm{CHCl}_{3} \cdot 0.5 n \mathrm{H}_{2} \mathrm{O}$. $\left[\mathrm{Cu}_{2}(\text { hfacac })_{4}(2)\right]_{n} \cdot n \mathrm{MeC}_{6} \mathrm{H}_{5} \cdot 2 n \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Cu}_{2}(\mathrm{hfacac})_{4}(2)\right]_{n} \cdot 2.8 n \mathrm{C}_{6}-$ $\mathrm{H}_{5} \mathrm{Cl}$ are isostructural. In all assemblies, the bis( $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy) ligands coordinate four $\left[\mathrm{M}(\mathrm{hfacac})_{2}\right](\mathrm{M}=\mathrm{Cu} ; \mathrm{M}=\mathrm{Zn})$ units directing the formation of planar (4,4)-nets, with the centroids of the phenylene spacers of $\mathbf{1}$ or $\mathbf{2}$ acting as nodes and the metal ions working as linkers.

In the copper(II) coordination polymers the metal ions display a trans-arrangement of the N -donor atoms. Differences, such as phenylalkoxy chain length or conformational changes in the $3,2^{\prime}: 6^{\prime}, 3^{\prime \prime}$-tpy groups, do not change significantly the motif and distinct features remain identical within the series. The $\mathrm{Cu}($ (I) centres are located near or in the plane (determined by the nodes) and the phenylalkoxy chains are directed outwards from the individual sheets. By contrast, in $\left[\mathrm{Zn}_{2}(\mathrm{hfacac})_{4}(\mathbf{1})\right]_{n} \cdot n \mathrm{MeC}_{6}{ }^{-}$ $\mathrm{H}_{5} \cdot 1.8 n \mathrm{CHCl}_{3}$, the $\mathrm{Zn}($ II $)$ centres have a cis-arrangement of the N atoms and are arranged alternately above and below the network. Pairs of 2-phenylethoxy tails are lodged in each cavity of the (4,4)-net interacting with each other via face-toface $\pi$-interaction.

This work showed that the assembly of planar (4,4)-nets by combining ligands 1 or 2 with $\left[M(\text { hfacac })_{2}\right] \cdot x \mathrm{H}_{2} \mathrm{O}(M=\mathrm{Cu}$, $x=1 ; \mathrm{M}=\mathrm{Zn}, x=2$ ) is independent upon the choice of the crystallization solvents. A switch from $\mathrm{Cu}(\mathrm{II})$ to $\mathrm{Zn}(\mathrm{II})$ influences the orientation of the metal linkers but does not change the topology of the network.

## Author contributions

Methodology and data analysis: G. M.; crystallography: A. P. and B. S.; PXRD: G. M.; supervision, project administration and funding acquisition: E. C. C. and C. E. H.; writingoriginal draft, G. M.; writing-review and editing: all authors. All authors have read and agreed to the published version of the manuscript.
