Prof. Dr. Clément Mazet

Basel, den 18.10.2022

Prof. Dr. Marcel Mayor

## Acknowledgements

I would like to acknowledge my supervisor Prof. Dr. Olivier Baudoin for accepting me as a Master student and for my Doctoral studies. The stay in his group at the University of Basel has allowed me to work on interesting and challenging chemistry and therefore grow as a chemist and as a person.

I would like to thank Prof. Dr. Christof Sparr for the great support as second supervisor throughout my PhD studies. I am grateful for the interesting and helpful inputs that made me think “outside the box” and overcome many obstacles.

I thank Prof. Dr. Clément Mazet for accepting the co-examination of this doctoral thesis and Prof. Dr. Andreas Pfaltz for chairing the PhD defence.

I thank Dr. Matthew Wheatley for tirelessly proofreading the present Doctoral thesis. Since you joined the Baudoin group, it has been a blast to work with you. Thank you for the great chemistry discussions and for the numerous laughter we had together.

I am grateful to my brother Dr. Giuseppe Zuccarello, who also greatly contributed to the proofreading of this Manuscript. Having a chemist in the family is a luxury that not everyone can have. Thank you not only for the great support and discussions in chemistry but also for having the right answer for all my questions in life.

I would like to express my gratitude to Dr. Stefania Vergura for proofreading one of the chapters and for the great time we had inside and outside the lab. Despite our “difficult” start, I much enjoyed working with you and I am happy that our paths crossed in the Baudoin group.

I thank Dr. Romain Melot, who supervised me during my Master project and for the further collaboration at the start of my PhD studies. I was very lucky to learn from a very talented and creative chemist, which greatly facilitated the beginning of my PhD studies.

With that, I would also express my gratitude to David Savary and Yann Baumgartner, who were always available for discussions during my Master and Doctoral studies. I really much enjoyed also the time outside the lab with the both of you and I am looking forward to many more years of friendship.

The stay in the lab 208 was unique and I will keep it as a special memory. In particular, I would like to thank Dr. Antonin Clemenceau with whom I had a fresh new start in a somewhat tired lab. Then, I thank Takeru Miyakoshi, who joined shortly after, for the great moments and for teaching me many things about the Japanese culture. It helped me to stay calm and keep a clear mind in difficult situations. I would also like to thank Rafael Lombardi who joined the lab the last and kept the high standards. Your readiness to help others is unique and the time with you inside but also outside the lab has always been great.

I am grateful for the time I spent with past and present group members. Your contributions have been key to the success of this thesis.

The Secretaries Marina Mambelli-Johnson and Nathalie Plattner-Longhi have never hesitated to support me with important bureaucracy that unfortunately still remains a part of a PhD study. I therefore thank you for your great helpfulness.

I thank the “Werkstatt-Team” consisting of Hisni Meha, Andreas Sohler and Marcus Ast, who worked tirelessly on the maintenance of the building, making sure that our research would never come to a stop.

Ringrazio I miei genitori Lina Cuturi e Antonino Zuccarello per il loro sostegno durante il dottorato. Grazie per tutti i sacrifici che avete fatto per me durante tutta la mia vita rendendo possibile di portare a termine tutti i miei studi fino al giorno d'oggi.

The results discussed in this doctoral thesis were published in:

# Prologue

The present doctoral thesis is subdivided into five main parts including one chapter on general introduction, three chapters describing research results and one general conclusion. At the beginning of each research chapter, a specific introduction into the topic is provided followed by results and discussion and a conclusion. The structures and references are numbered continuously throughout the thesis. The experimental section is found at the end of the thesis.

**Chapter 1:** gives an introduction on fundamental aspects of transition metal catalyzed C–H activation and summarizes the most successful and pivotal examples for the development of the intramolecular Pd(0)-catalyzed C–H activation reaction to form small- and medium-sized rings.

**Chapter 2:** presents the design and optimization of a new Pd(0)/NHC\* catalytic system for the activation of secondary C–H bonds to form chiral indanes. The project was developed in collaboration with Romain Melot, Diana Cavalli and Nadja Niggli. The presented results are published in *Angew. Chem. Int. Ed.* **2021**, *60*, 7245–7250.

**Chapter 3:** discusses the influence of  $\alpha$ -substituents on the reactivity of C(sp<sup>3</sup>)–H bonds based on differences in initial rates. Kinetic analysis of the reaction showed that the C–H abstraction step is rate-limiting, thus confirming that the comparison is relevant. The study was conducted in collaboration with Dr. Matthew Wheatley and his results are included in the chapter. At the time of writing this thesis, the manuscript is in preparation.

**Chapter 4:** describes preliminary results on the optimization of an enantioselective Pd(0)/L\* catalytic system to activate remote C(sp<sup>3</sup>)–H bonds enabled by 1,4-Pd shift. This strategy has seen significant developments over the past 5 years and complements the direct Pd(0)-catalyzed C–H activation methods in terms of structures that can be prepared.

A **General conclusion** is provided at the end of this thesis.

## Abstract

Direct transition metal catalyzed C–H bond functionalization has emerged as a powerful strategy to form new C–C or C–X bonds over the past decades. Advantages such as no requirement for pre-functionalization of the reagents and therefore the reduced metal waste makes it an attractive alternative to the well-established cross-coupling reactions. In this regard, Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation has been applied in the past for the construction of complex molecules and in numerous total syntheses of natural products. In addition, elegant enantioselective methodologies have granted access to important scalemic products for the pharmaceutical and agrochemical industry. However, most of these methods rely on the desymmetrization of prochiral alkyl groups leading to the formation of the stereogenic center distal to the activation site. The activation of enantiotopic secondary C–H bonds remains underdeveloped, mainly attributed to their low intrinsic reactivity, with only one report on the synthesis of  $\beta$ -lactams.

To address this long-standing challenge, a highly reactive Pd/NHC catalytic system was design and optimized for the synthesis of chiral indanes. A variety of products were obtained in good to high yields and high enantioselectivities using IBioxR NHC ligands developed by the Glorius group. Furthermore, the first synthesis of chiral 3<sup>ary</sup> amides by Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation was described in consistent high enantioselectivities. Moreover, a stereochemical analysis provided valuable insights on the relationship between ligand structure and enantioinduction.

Mechanistic studies were performed on the newly developed Pd/NHC catalyzed activation of methylene C–H bonds to examine the selectivity trends observed in the course of the development of the Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation reaction. For instance, primary C–H bonds are preferentially activated over secondary C–H bonds or the selectivity between C–H bonds is altered by changing the substituent in  $\alpha$ -position. In contrast to C(sp<sup>2</sup>)–H bond activation, where the use of Hammet plots has helped to quantify the influence of substituents with different electronic properties on the C–H activation process, the design and development of new C(sp<sup>3</sup>)–H activation methods has been mainly guided by chemical intuition. In this context, a reactivity scale was constructed putting C(sp<sup>3</sup>)–H bonds differing in  $\alpha$ -substitution on a series of most to least reactive by performing initial rate experiments. Prior kinetic isotope studies and kinetic analysis of the reaction to obtain the orders in reaction components confirmed the C–H activation step to be rate-limiting, thus suggesting that the comparison of the different C–H bonds is significant.

The activation of remote C(sp<sup>3</sup>)–H bonds enabled by 1,4-Pd shift has experienced significant growth in the past 5 years. With this strategy new type of complex molecules, lacking structural motifs promoting the ring closure otherwise required for direct C–H activation, could be synthesized. Nevertheless, no enantioselective methods are reported to this date. To this end, new substrates were designed and synthesized and preliminary screening of chiral ligand families previously applied in direct enantioselective Pd(0)-catalyzed C–H activation was undertaken to contribute to the progress of asymmetric remote C(sp<sup>3</sup>)–H activation.

## General Objectives

The objectives of this Doctoral Thesis include the development of an enantioselective method for the activation of secondary C–H bonds under Pd(0) catalysis and the study of the operative mechanism. In particular, our investigations focused on:

- The synthesis of enantioenriched indanes and amides featuring a tertiary  $\alpha$ -stereogenic center using chiral IBiox-type ligands.
- The correlation between steric properties of the ligands and enantioselectivity.
- The effect of  $\alpha$ -substitution on the reaction rate employing the visual kinetic analysis method variable time normalization.

# Chapter 1: Introduction

## 1.1 General aspects

### 1.1.1 Cross-coupling reactions to form C–C and C–X Bonds

Synthetic organic chemistry is driven by the formation of new chemical bonds to construct highly complex molecules from simple and abundant building blocks. In particular, the formation of C–C bonds is of central importance. A major historical milestone was set with the discovery of catalytic cross-coupling reactions complementing classical functional group interconversion chemistry. In fact, the pioneering efforts by Heck, Suzuki and Negishi on Pd-catalyzed cross-couplings was awarded with the Nobel prize in 2010.<sup>[1,2]</sup> The general catalytic cycle for this transformation starts with the oxidative addition of the active  $M^0$  species into the carbon–halogen (or pseudo halogen) bond of substrate **1.1** leading to the formation of oxidative addition complex **1.2** (Scheme 1.1). Then, transmetalation with a nucleophilic coupling partner, typically of structure R–Y, gives intermediate **1.3**, which upon reductive elimination is transformed to the desired product and the catalytic active  $M^0$  species is restored.

**Scheme 1.1:** General catalytic cycle for cross-coupling reactions.

To date, cross-coupling reactions have been expanded to C–heteroatom bond formation<sup>[3,4]</sup> and catalysts based on transition metals such as Ni,<sup>[2]</sup> Co,<sup>[5]</sup> Fe<sup>[2]</sup> and Cu<sup>[3,4,6,7]</sup> have been employed with numerous applications in the total synthesis of natural products,<sup>[8]</sup> medicinal chemistry, agricultural chemistry and ton-scale industrial processes. However, despite the great utility of this extremely powerful tool, major drawbacks include the use of expensive metal-containing reagents and the high quantities of toxic metal waste that comes with it. Thus, finding more environmentally friendly and cheaper alternatives has been a long-standing challenge.

### 1.1.2 The Hoffmann-Löffler-Freytag reaction-early advances in C–H bond functionalization

Organic molecules consist of linear or cyclic consecutive hydrocarbon motifs, interrupted by heteroatoms such as nitrogen, oxygen, sulfur and phosphorus. Thus, C–H bonds are omnipresent in organic chemistry and their direct and selective functionalization to form new C–C, C–O, C–N and C–X bonds constitute a step economical and sustainable alternative to cross-coupling chemistry. Molecular diversity can be easily achieved by selective

functionalization of distinct C–H bonds based on electronic and steric properties on a complex precursor, facilitating late-stage functionalisation of active compounds.<sup>[9,10]</sup> Additionally, direct C–H functionalization eliminates the preparation of metal containing coupling partners as required for cross-couplings, thus significantly reducing, synthetic steps, toxic waste and costs. Early advances in C–H bond functionalization were made by Hoffmann showing that homolysis of bromo- and chloroamines led to cyclization with methylene or methyl groups. Homolysis of the N–Br bond on substrate **1.5** forms a highly reactive *N*-centered radical, which subsequently triggers a 1,5 hydrogen atom transfer (HAT) to form **1.7** after recombination. The ring is then closed by nucleophilic substitution completing the synthesis of nicotine (**1.8**, Scheme 1.2a). Similarly, conanine alkaloids were prepared by Buchsacher and Jeger<sup>[11]</sup> by subjecting substrate **1.9** to a mixture of sulfuric and acetic acid. Although this reaction proceeds through an unstable primary radical intermediate **1.11**, the 1,5-HAT is facilitated by the structural preorganisation of the molecule (Scheme 1.2b). In the same year, Corey reported the synthesis of the structural related dehydroconessine employing similar reaction conditions.<sup>[12]</sup>

**Scheme 1.2:** Early applications of the Hoffmann-Löffler-Freytag reaction.

This transformation, to date known as the Hoffman-Löffler-Freytag reaction, set the fundament for the consideration of inherently inert C–H bonds as a retron for various functional groups.

### 1.1.3 Transition metal-catalyzed C–H functionalization

#### 1.1.3.1 general mechanisms

In the past decades, transition metal-catalyzed C–H functionalization has experienced significant advancement as it constitutes an elegant strategy to introduce molecular complexity starting from simple substrates. However, as most organic molecules possess several C–H bonds, the selective functionalization of one C–H bond over the other remains highly challenging. As described by Sanford,<sup>[13]</sup> two main mechanisms are operative in transition metal-catalyzed C–H functionalization. (1) In the “*inner-sphere*” mechanism, an organometallic intermediate of structure **1.13** is formed after C–H bond cleavage (Scheme 1.3a). Regio- and stereoselectivity of functionalization are driven by structural and electronic properties of the formed intermediate. In this type of transformation high selectivity for the less hindered C–H bond is observed. However, the selectivity can be influenced not only by the mechanism of the C–H bond cleavage but also the ligand environment on the metal centre. This mechanism is encountered in C–H activation processes but also in the oxidative addition into C–H bonds and  $\sigma$ -bond metathesis.<sup>[14]</sup>

**Scheme 1.3:** a. Inner-sphere mechanism. b. Outer-sphere mechanism.

(2) The “outer-sphere” mechanism is reminiscent of biological oxidation reactions catalyzed by cytochrome P450 and methane monooxygenase.<sup>[15,16]</sup> Initially, a high oxidation state metal complex **1.15** is formed possessing an activated ligand X (Scheme 1.3b). The ligand then reacts with the C–H bond of substrate **1.12** either by direct insertion (path **I**) or H-atom abstraction/rebound (path **II**). As opposed to the inner-sphere mechanism, the substrate directly reacts with the ligand and not with the metal center. In this case the selectivity is driven by the build-up of cationic or radical character and therefore weaker bonds such as benzylic, allylic, 3<sup>ary</sup> or in  $\alpha$ -position to heteroatoms are cleaved preferentially. Typical reactions proceeding over an outer-sphere mechanism are carbenoid<sup>[17,18]</sup>/nitrenoid<sup>[19,20]</sup> C–H insertion<sup>[17,18]</sup> and C–H bond oxidation.<sup>[21,22]</sup>

### 1.1.3.2 Transition metal-catalyzed C–H bond activation

Labinger and Bercaw<sup>[23]</sup> defined C–H bond activation as a process where a distinct C–[M] bond is formed after cleavage of a C–H bond. Thus, C–H activation falls into the category of inner-sphere mechanisms of C–H functionalization (see section 1.1.3.1, Scheme 1.3a). Depending on the nature of the substrate, five different mechanisms have been widely accepted.<sup>[24,25]</sup> (1) In the *oxidative addition* mechanism the metal species oxidatively inserts into the carbon-hydrogen bond of **1.12** leading to transition metal intermediate **1.20** (Scheme 1.4a).

**Scheme 1.4:** Mechanisms of C–H bond activation.

(2)  *$\sigma$ -Bond metathesis* proceeds through 4-membered transition state **1.22** leading to the formation of intermediates **1.23** and **1.24**. This pathway is generally preferred by early transition metals (Scheme 1.4b). (3) During the

*electrophilic substitution* mechanism the metal species is attacked by aromatic or unsaturated substrate **1.26** forming a positively charged metal intermediate **1.27**. Abstraction of the proton gives structure **1.28**. (4) In the *base assisted mechanism* a carboxylate or carbonate ligand is involved in the proton abstraction over a concerted process forming cyclic transition state **1.30**. To date, this mechanism is known as concerted metalation deprotonation (CMD) or ambiphilic metal–ligand activation (AMLA).<sup>[26,27]</sup> Finally, (5) the *Hack-type* mechanism begins with 1,2-insertion of organometallic species **1.21** into aromatic structures of type **1.32** leading to intermediate **1.33**. After isomerization, structure **1.34** is formed with the metal and hydrogen substituents in *syn* relationship to each other.  $\beta$ -H Elimination gives then functionalized product **1.35** and metal-hydride species **1.36**.

Additionally, transition metal catalyzed C–H activation reactions can be further subdivided in three different classes.<sup>[28]</sup> (1) *Directed C–H activation* reactions rely on the coordination of the active catalyst to a Lewis-basic acceptor tethered to the substrate (**1.37**). Upon coordination of the metal structure **1.38** is formed which is transformed to product **1.39** by functionalization (Figure 1.1a). Typically, monodentate amides, pyridines, esters or imines as well as bidentate directing groups are utilized to ensure selectivity.<sup>[29]</sup> This strategy, although not ideal as often the directing group is not part of the desired product, it is the most widespread one. However, recent efforts have been focused on the use of transient directing groups, which are attached to the substrate *in situ* and cleaved after C–H activation.<sup>[30–35]</sup> (2) *Non-directed* or *undirected C–H activation* exploits the innate reactivity of the substrate. Selectivity is thereby guided by factors such as electronic properties of the C–H bond and steric hindrance. This method is more attractive since the installation and removal of a directing group can be avoided. Instead, the metal catalyst interacts directly with the C–H bond of substrate **1.40** forming metal complex **1.41**. Product **1.14** is then obtained after functionalization (Figure 1.1b). However, this transformation suffers from major drawbacks such as high catalyst loadings, harsh conditions and often difficult separations due to lower selectivity leading to mixtures of unseparable products. (3) Finally, in the third type of activation reactions the transition metal catalyst oxidatively inserts into a C–LG (LG = leaving group, halogens or pseudohalogens) bond of the substrate to form complex **1.43**, hence the name *oxidative addition-induced C–H activation* (Figure 1.1c). The oxidation state of the metal is thereby increased by two units and an external base is used to abstract the desired proton and form metalated complex **1.44**. Upon functionalization and reductive elimination product **1.45** is formed and the metal catalyst is reduced to its initial oxidation state.<sup>[25,36]</sup>

**Figure 1.1:** Different classes of C–H bond activation reactions. a. Directed C–H activation b. Undirected C–H activation. c. Oxidative addition-induced C–H activation.

## 1.2 Pd-catalyzed C–H bond activation

Palladium is arguably one of the most widely used transition metals for C–H bond activation reactions and has been thoroughly reviewed in several articles.<sup>[36–39]</sup> This is mainly attributed to its ability to operate under several catalytic manifolds such as Pd(II)–Pd(0), Pd(II)–Pd(IV), and Pd(0)–Pd(II) among others.<sup>[38]</sup> The two first are more widespread in directed C–H activation reactions. Typically, the Pd(II)–Pd(0) catalytic cycle starts with the activation of the C–H bond of substrate **1.47** leading to palladated species **1.48**. Ligand exchange, usually by trans metalation gives intermediate **1.50** from which product **1.51** is formed by reductive elimination (Scheme 1.5a). The resulting Pd(0) species is oxidized to regenerate catalytic active Pd(II) by an external oxidant. Similarly, the first step in the Pd(II)–(IV) manifold is the C–H activation of substrate **1.47** giving intermediate **1.48**. The functional group is then introduced to the catalyst by an oxidative process leading to Pd(IV) intermediate **1.56**. Product **1.51** is formed by reductive elimination releasing the catalytically active Pd(II) species (Scheme 1.5b).

**Scheme 1.5:** Catalytic cycles of Pd-catalyzed C–H activation. a. Pd(II)–Pd(0) catalysis. b. Pd(II)–Pd(IV) catalysis. c. Pd(0)–Pd(II) catalysis.

The Pd(0)–Pd(II) manifold is generally operative in non-directed or intramolecular oxidative addition induced C–H activation (Scheme 1.5c). In this particular case the catalytic cycle begins with the oxidative addition of the Pd(0) species into C–X bond (X = (pseudo-) halogen) of substrate **1.57** generating Pd(II) intermediate **1.58**. After ligand exchange, C–H bond activation leads to cyclopalladated species **1.60** from which the product is obtained by reductive elimination with concomitant reduction of the Pd(II) to the active Pd(0) species. Notably, in all three

cases the C–H activation reaction occurs from the Pd(II) species. Although the three manifolds are well established in C–H activation transformations,<sup>[24,39]</sup> the main focus of this introduction is the Pd(0)-Pd(II)-catalyzed intramolecular C–H activation.

### 1.2.1 Pd(0)-catalyzed intramolecular C(sp<sup>2</sup>)–H bond activation for the formation of small- to medium-sized rings

The first example of Pd(0)-catalyzed activation of C(sp<sup>2</sup>)–H bonds was reported by Ames in 1982.<sup>[40]</sup> Reacting cinnouquinoline **1.62a** in presence of catalytic Pd(OAc)<sub>2</sub> and ethyl acrylate gave dibenzofuranyl **1.63a** in 19% yield instead of the expected alkenylation at the 3-position (Scheme 1.6). A similar reaction outcome was observed with **1.62b** giving product **1.63b** in 55% yield. In absence of ethyl acrylate no product formation was observed presumably, because the acrylate is responsible for the reduction of the Pd(II) precatalyst to the Pd(0) active species. Later, examples for the formation of 5 and 6 membered rings from the corresponding aryl iodides and arylbromide precursors were presented.<sup>[41,42]</sup> Substituted dibenzofurans (**1.64a-c**), carbazole-1-carboxylic acid **1.65**, fluorenone **1.66**, lactone **1.67** and lactam **1.68** were prepared in good to high yields.

**Scheme 1.6:** early contributions to Pd(0)-catalyzed C(sp<sup>2</sup>)–H activation.

The first application in the total synthesis of ancistrocladisine (**1.72**) was reported by the Bringmann group in 1989 (Scheme 1.7). Starting from substituted phenol **1.69**, substrate **1.70** for the Pd(0)-catalyzed C(sp<sup>2</sup>)–H activation was reached by Pictet-Spengler reaction with acetaldehyde and acylation of the phenol with the corresponding naphthoyl chloride. Subjecting **1.70** to catalytic amount of Pd(PPh<sub>3</sub>)<sub>2</sub>Cl in presence of NaOAc afforded **1.71** in 87% yield. The synthesis was completed by opening of the lactone ring, epimerization

**Scheme 1.7:** First application of Pd(0)-catalyzed C(sp<sup>2</sup>)-H activation: total synthesis of ancistrocladisine (**1.72**).

deprotection and imine formation. Although other examples of applications into the synthesis of important natural products were demonstrated by the Bringmann group<sup>[43,44]</sup> the scope of the method is limited and relies on harsh conditions including temperatures up to 190 °C.

Fagnou introduced the use of Buchwald-type ligands for the intramolecular arylation of C(sp<sup>2</sup>)-H bonds.<sup>[45]</sup> Substrates of type **1.73** readily cyclised to tricyclic products **1.74** with high efficiency under catalyst loadings as low as 0.1 mol% Pd(OAc)<sub>2</sub> and 0.2 mol% of ligand **L1.1** (Scheme 1.8a). A broad scope of products featuring electron-donating (**1.74b**) and -withdrawing (**1.74c**) groups on the aromatic ring was presented. Additionally, the oxygen on the tether could be changed to a nitrogen or carbon (**1.74d**). The formation of a 7-membered ring (**1.74f**) was achieved by introducing an electron-withdrawing group in position of the dimethyl amino group on the biaryl ligand.

**Scheme 1.8:** a. Highly efficient C(sp<sup>2</sup>)-H arylation using Buchwald-type ligands. b. Application in total synthesis of (*R*)-Nuciferine (**1.77a**) and (*R*)-Normuciferine (**1.77b**).

This improved protocol was applied in the total synthesis of aporphine alkaloids (Scheme 1.8b).<sup>[46,47]</sup> From substrates **1.75a** and **1.70b** differing in the protecting group of the amine, the corresponding tetracyclic cores **1.76a** and **1.76b** were obtained by C(sp<sup>2</sup>)-H activation in 84% and 80% yield respectively. (*R*)-Nuciferine (**1.77a**) was then accessed by reduction of the CO<sub>2</sub>Me protecting group of **1.76a** with LiAlH<sub>4</sub>. Similarly, deprotection of the CO<sub>2</sub>tBu group on **1.76b** gave (*R*)-Nornuciferine (**1.77b**) in remarkable 90% yield. After this report, the field experienced a strong growth and several methods relying on the Pd(0)-catalyzed activation of C(sp<sup>2</sup>)-H activation were disclosed.<sup>[25,48]</sup>

An important milestone was reached with a thorough mechanistic study of Echavarren and Maseras on the formation of phenanthrenes.<sup>[49,50]</sup> Subjecting substrates of type **1.78** under the conditions optimized by Fagnou and subsequent treatment with DDQ gave either product **1.79** or **1.80** depending on the nature of the R substituent on the aromatic ring (Scheme 1.9). It was found that when R was electron-withdrawing cyclisation preferentially occurred with the substituted aromatic ring giving product **1.79**. Conversely, product **1.80** was observed when R was of electron-donating nature. This is in disagreement with the electrophilic palladation mechanism originally thought to be operative. With density functional theory (DFT) calculations direct  $\sigma$ -bond metathesis (**TS1**) could be ruled out based on the high energy of 43.3 kcal mol<sup>-1</sup>. Instead, a base-assisted proton abstraction mechanism either inter- or intramolecular (**TS2** and **TS3**) was found plausible.

Echavarren & Maseras 2006

**Scheme 1.9:** Formation of phenanthrenes **1.79** and **1.80** and calculated transition states for C(sp<sup>2</sup>)-H arylation.

Enantioselective C(sp<sup>2</sup>)-H activation methods rely on the desymmetrization of prochiral substrates forming the stereogenic center distal to the C-H activation site or on the formation of a chiral axis or plane. The first example of asymmetric C(sp<sup>2</sup>)-H activation was reported by the Cramer group in 2009.<sup>[51]</sup> Alkenyl triflates **1.81**, easily accessed from ketone precursors, were subjected to Pd(0) catalysis with chiral taddol-based phosphoramidite ligand **L1.2a** furnishing indanes **1.82** in high yields and enantioselectivities (Scheme 1.10a). Later the desymmetrization of arylbromide substrates of type **1.83** to form 7-membered rings using a similar phosphoramidite ligand **L1.2b** was demonstrated by the same group. In this case, the reaction proceeds through a thermodynamically unfavoured 8-membered palladacycle. Dibenzazepinone products **1.84** featuring a quaternary stereogenic center were obtained in excellent yields and enantioselectivities.

**Scheme 1.10:** First report of enantioselective C(sp<sup>2</sup>)-H activation.

The Baudoin group reported the use of bifunctional ligands for enantioselective C(sp<sup>2</sup>)-H activation. Binaphthalene derived phosphine ligands **L1.3** featuring a carboxylic acid substituent on the aromatic scaffold are responsible for both, proton abstraction and enantioinduction (Scheme 1.11a). Substrates **1.85** were efficiently converted to dihydrophenanthridines **1.86** with high selectivities of up to 98.5:1.5 e.r. It was found that the length of the linker of the carboxylic acid to the aromatic ring has an impact on the enantioselectivity. The e.r. value decreased with increasing chain length of the linker. The control experiments with 1.0 equivalent of the potassium salt derived from ligand **L1.3a** omitting Cs<sub>2</sub>CO<sub>3</sub> showed that the product was formed in comparable yield and selectivity. This result suggests that the ligand is operating in bifunctional mode and that Cs<sub>2</sub>CO<sub>3</sub> is not involved in the proton abstraction process. Additionally, parallel kinetic resolution from racemic mixtures of **1.85** bearing different aromatic groups undergoing C-H activation was achieved leading to the formation of two enantioenriched products. A similar protocol was employed in the synthesis of highly strained fluoradenes **1.87** and other warped molecules of type **1.88** by the same group (Scheme 1.11b).

**Scheme 1.11:** Binaphthalene-derived bifunctional ligands as enantioinductor and active base.

The use of electrophiles other than aryl- or alkenyl(pseudo-)halides were reported by the Cramer and Tang group. In 2017 the reaction of ketene aminal phosphates **1.89**, which are more stable than triflate derivatives, to chiral isoindolines **1.90** was reported.<sup>[52]</sup> With electron-rich phospholane ligand **L1.4** high yields and selectivities were obtained at room temperature (Scheme 1.12a). Interestingly, when the reaction was conducted under carboxylate free conditions, i.e. Pd(dba)<sub>2</sub> without PivOH, traces of the product were still observed indicating that the diphenyl phosphate anion acts as a poor active base. Moreover, a rare example of Pd(0)-catalyzed parallel

kinetic resolution was demonstrated. Shortly after, the same group reported the synthesis of 1*H*-isoindoles **1.92** bearing highly congested quaternary stereogenic centers from perfluoroalkyl-substituted imidoyl chlorides **1.91** (Scheme 1.12b).<sup>[53]</sup> The products could be further elaborated by reducing or nucleophilically attacking the imine moiety. The Tang group reported the synthesis of chiral isoindolines **1.94** from carbamoyl chloride precursors of type **1.93** using (*R*)-Antphos previously developed in the same group. In this case, CO pressure was essential to prevent decarbonylation of the starting materials and ensure high yields and selectivities (Scheme 1.12c).<sup>[54]</sup>

**Scheme 1.121:** Use of alkenylphosphate (a), imidoyl chlorides (b) and acyl chlorides (c) as electrophiles.

In addition to the formation of carbon stereogenic centers, methods to synthesize *Si*- and *P*-stereogenic compounds have been developed over the past decade.<sup>[55]</sup> An early example is the synthesis of chiral dibenzosiloles **1.96** featuring an *Si*-stereogenic center from triflate precursors **1.95** reported by Hayashi and Shintani.<sup>[56]</sup> Not only was the bidentate phosphine ligand (*R,S*<sub>p</sub>)-**L1.6** responsible for high enantioselectivities, it also suppressed the formation of achiral **1.97** arising from a 1,5-Pd shift mainly formed with monodentate ligands screened during this study (Scheme 1.13a). In 2015, Duan<sup>[57]</sup> and Ma<sup>[58]</sup> simultaneously disclosed the synthesis of *P*-stereogenic phosphinic amides **1.97** by desymmetrization of aryl bromides **1.98** (Scheme 1.13b). With almost identical taddol-derived phosphoramidite ligands **L1.2b** and **L1.2b** the products were obtained in excellent yields and enantioselectivities in both cases. Similar tricyclic *P*-stereogenic phosphonates **1.99** were also reported by the Tang group using Antphos-type ligand **L1.6** (Scheme 1.13c).<sup>[59]</sup>

**Scheme 1.13:** Syntheses of Si- and P-stereogenic compounds: a. benzosiloles **1.96**, b. phosphinic amides **1.98** and c. phosphonates **1.99**.

Cui and Xu,<sup>[60]</sup> and Duan<sup>[61]</sup> reported the synthesis of *P*-stereogenic phosphole oxides **1.101** (Scheme 1.14). Bidentate phosphine ligands (*S,S*)-Duphos and (*R*)-Segphos furnished the products in high yields and enantioselectivities. Moreover, Duan also demonstrated that chiral binol-derived phosphoric acids and amides can induce enantioselectivity in presence of a non-chiral ligand as a part of the same study.

**Scheme 1.14:** Enantioselective arylation of phosphine oxides **1.95** to phosphole oxides **1.96**.

The synthesis of planar chiral metallocenes by Pd(0)-catalyzed C(sp<sup>2</sup>)-H activation was reported by several groups. The formation of cyclic lactams **1.102** and **1.103** was reported by the Gu group<sup>[62]</sup> and Liu & Zhao<sup>[63]</sup> in 2014. Although the protocol of Gu was compatible with both ferrocenes and ruthenocenes, the use of (*R,S*<sub>a</sub>)-OPINAP led to moderate enantioselectivities. Conversely, higher enantioselectivities (up to 97:3 e.r.) were reported by Liu and Zhao employing phosphoramidate ligand **L1.2c** (Scheme 1.15a). A major improvement was made by introducing chiral bidentate phosphine ligand BINAP as enantioinductor for the formation of 5-membered rings in the same year. Gu-You<sup>[64]</sup> and Kang-Gu<sup>[65]</sup> independently reported the same reaction forming ferrocenes **1.104** and metallocenes **1.105** in excellent yields and enantioselectivities. Later, the synthesis of ferrocenylpyridines **1.106**<sup>[66]</sup> and C(sp<sup>2</sup>)-H alkenylation<sup>[67]</sup> to form ferrocenes of type **1.107** was reported by the same group (Scheme 1.15b).

**Scheme 1.15:** Synthesis of planar chiral metallocenes. a. Formation of 6-membered rings. b. Formation of 5-membered rings.

The Guiry group presented the synthesis of planar, central and axially chiral ferrocenyl diols by applying the protocol disclosed by Gu and You.<sup>[68]</sup> Although the preparation of **1.109** from precursor **1.108** by two-fold C–H activation was already reported in the study of the reaction scope, the Guiry group slightly modified the reaction conditions to obtain a quantitative yield. 18 different ferrocenyl diols of type **1.110** were prepared by reacting **1.109** with the corresponding organo-lithium or -Grignard reagents (Scheme 1.16). Ferrocenyl diols **1.110** were applied as catalysts in the asymmetric hetero-Diels-Alder reaction leading to moderate to high enantioselectivities.

**Scheme 1.16** Synthesis of ferrocenyl diols.

More recently, the Duan group reported the synthesis of planar chiral benzothiophene-fused ferrocenes **1.112**.<sup>[69]</sup> In the presence of bidentate (*R*)-segphos, ferrocenyls **1.111** were efficiently arylated to the corresponding products in high yields and enantioselectivities. Moreover, planar chiral benzothiophene-fused ferrocene **1.112a** featuring a phosphinoyl substituent on the lower Cp ring was reduced to the corresponding phosphine **1.112aa** and engaged in cross-coupling chemistry. The Suzuki-Miyaura coupling between aryl bromide **1.113** and boronic acid **1.114** using **1.112aa** as chiral ligand led to the formation of biaryl **1.115** in good yield and moderate enantioselectivity (Scheme 1.17).

**Scheme 1.17:** Synthesis of planar chiral benzothiophene-fused ferrocenes **1.107** and application in the Suzuki-Miyaura cross-coupling.

Enantioselective intramolecular Pd(0)-catalyzed C(sp<sup>2</sup>)-H activation reactions for the synthesis of molecules with chiral axes are more scarce and only two protocols have been presented in the past 5 years. In 2017 The Gu group demonstrated the atroposelective synthesis of indole-based biaryls **1.117** by dynamic kinetic C-H cyclization of substrates **1.116** (Scheme 1.18a). Using phosphoramite **L1.12d**, high yields of up to 99% and enantioselectivities of 95.5:4.5 were observed. The OMOM substituent on the naphthyl moiety was essential to ensure high enantioselectivities as with the less sterically demanding OMe the rotational barrier was too low. Shortly after, the Cramer group demonstrated the synthesis of axially chiral dibenzazepinones **1.119** using phosphoramidite **L1.2b** (Scheme 1.18b).<sup>[70]</sup> In contrast to the approach of Gu, in this case, the axis of chirality is formed during the C-H functionalization process by discrimination between enantiotopic faces of a phenyl group. *Ortho* and *meta* substitution on Ar<sup>1</sup> played an important role to ensure high levels of enantioselectivity as non-substituted products racemized withing 2 hours.

**Scheme 1.18:** Approaches for the synthesis of axially chiral molecules. A. Dynamic kinetic resolution. b. De novo formation of chiral axis.

### 1.2.2 Pd(0)-catalyzed intramolecular C(sp<sup>3</sup>)-H bond activation

The first observation of Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation was reported by Dyker in 1992 for the synthesis of structure **1.123** by self-condensation of three molecules of 2-iodoanisole **1.120** (Scheme 1.19).<sup>[71]</sup> They proposed the formation of cyclopalladated species **1.121** by activation of the OMe group. The new aryl-aryl bond on intermediate **1.122** is presumably formed by oxidative addition of a new molecule of **1.120** on intermediate **1.121** and subsequent reductive elimination leading to an overall 1,5-Pd shift to the OMe group.

Scheme 1.19: Early C(sp<sup>3</sup>)-H activation reactions.

Later, the same group reported the formation of benzocyclobutenes **1.128** by activation of *t*Bu groups. In analogy to the previous report, the activation of the *t*Bu group leads to cyclopalladated species **1.125** followed by oxidative addition of another molecule of starting material to give intermediate **1.126**. Reductive elimination gives structure **1.127** from which product **1.128** is formed by a second C-H activation/reductive elimination sequence.

In 2003, the Baudoin group reported the use of phosphine ligands for Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation which prevented the self-condensation of the starting material by suppressing competitive oxidative addition to Pd<sup>II</sup> intermediates.<sup>[72]</sup> Depending on the nature of the starting materials **1.129** either olefins **1.130** or benzocyclobutenes **1.131** were formed (Scheme 1.20a). The proposed pathway for the formation of the olefin products proceeds through the formation of 6-membered palladacycle **1.132** and subsequent β-H elimination and reductive elimination. In the case of the benzocyclobutenes direct reductive elimination from 5-membered intermediate **1.133** forges the 4-membered ring. In 2007 the same group reported improved reaction conditions for the selective dehydrogenation of alkanes using the newly designed F-TOTP (tris(5-fluoro-2-mehtylphenyl)phosphane) ligand (Scheme 1.20b).<sup>[73]</sup> Additionally, with the new reaction conditions product **1.130a** was obtained in 82% yield and was further elaborated to the antihypertensive drug verapamil (**1.134**).

**Scheme 1.20:** a. Preparation of olefins **1.130** or benzocyclobutenes **1.131** by Pd(0)-catalyzed C(sp<sup>3</sup>)-H functionalization. b. Application of improved protocol in the synthesis of verapamil (**1.134**).

After the initial report on alkane dehydrogenation of the Baudoin group several, methodologies for the formation of small- to medium-sized rings by arylation of C(sp<sup>3</sup>)-H bonds were reported and an overview is given in Scheme 1.21.<sup>[36]</sup> Examples for the formation of 4-membered rings include the formation of benzocyclobutenes **1.131** from aryl bromide precursors initially reported by the Baudoin group in 2008.<sup>[74]</sup> Later, similar products were prepared from cheaper and more abundant aryl chlorides.<sup>[75]</sup> Although benzazetidines **1.135** could never be isolated, benzoxazines **1.136** were formed by 4 $\pi$  electrocyclic opening of the 4-membered ring followed by a 6 $\pi$  electrocyclization of the aza-*ortho*-xylylene moiety with the carbonyl substituent on the nitrogen atom.<sup>[76]</sup> The formation of 5-membered rings was demonstrated as well by Baudoin and Fagnou in 2010 giving indanes, indolines or dihydro benzofuranes of type **1.137**. Examples of the more challenging methylene C(sp<sup>3</sup>)-H bond activation were reported by the group of Knochel<sup>[77]</sup> for the synthesis of strained tricyclic structures **1.138** and the Baudoin<sup>[73]</sup> group to access indanes **1.139**. Electron-rich trialkyl phosphine PCy<sub>3</sub> proved to be the ligand of choice for a selection of methods for the formation of 5-membered rings. In fact, dihydrobenzofurans **1.140**,<sup>[78]</sup> indolines **1.141**,<sup>[79]</sup> oxindoles **1.142** and sulphonamides **1.143**<sup>[80]</sup> could be prepared in good to high yields under similar conditions with PCy<sub>3</sub> as the ligand. Oxindoles **1.144** were accessed by activation of congested cyclopropyl C(sp<sup>3</sup>)-H bonds. Nevertheless, the products were obtained in good to excellent yields up to 14:1 d.r. Examples of 6-membered rings were presented by Knochel<sup>[77]</sup> (**1.145**) and Shi<sup>[81]</sup> (**1.146**). Remarkably, in the case of Shi, the unprotected nitrogen was compatible with the reaction conditions. Additionally, the Baudoin group reported the synthesis of tetracyclic structures **1.147** by simultaneous formation of a 6- and a 5-membered ring.<sup>[82]</sup> This strategy was applied in the total synthesis of lycorine alkaloids. Among others, ( $\pm$ )-lycorane (**1.148**) was prepared in 4 steps with an overall yield of 47%.

#### 4-membered rings

#### 5-membered rings

#### 6-membered rings

**Scheme 1.21:** Examples of Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation for the formation of 4-, 5-, 6-membered rings.

In analogy to Pd(0)-catalyzed C(sp<sup>2</sup>)-H activation, other electrophiles were used for the oxidative addition step. For instance, the Takemoto group reported the cyclization of carbamoyl chlorides **1.149** to the corresponding oxindole products **1.150** by activation of a benzylic methyl group (Scheme 1.22).<sup>[83]</sup> Similarly, the Baudoin group reported the synthesis of strained β-lactams **1.152** from carbamoyl chlorides **1.151**.<sup>[84]</sup> To prevent in situ decarbonylation of the starting material an excess of COgen was added using a two-chamber system developed by the Skrydstrup group.<sup>[85]</sup> In contrast to directly purging the reaction with CO as reported by Takemoto, the use of COgen requires fewer safety precautions. An alternative approach for the activation of benzylic C(sp<sup>3</sup>)-H bonds was reported by the Cramer group a few years later.<sup>[86]</sup> Indoles **1.154** were prepared from imidoyl chlorides **1.153** in good to high yields using either PCy<sub>3</sub> or SIPr as ligand. The latter was usually superior to PCy<sub>3</sub> in the case of 6-substituted imidoyl chlorides. The alkenylation of C(sp<sup>3</sup>)-H bonds from alkenyl(pseudo-)halide precursors is an attractive alternative to the arylation reactions as the double bond in the formed products can be easily reduced. Acyclic alkenyl bromide substrates **1.155** were efficiently converted to γ-lactams by the Baudoin group in 2016.<sup>[87]</sup> It was found that the substituent in α-position to the nitrogen is essential for high yields, presumably by inducing a significant Thorpe-Ingold effect that is necessary for the ring contraction. In the same year, the Takemoto group demonstrated the synthesis of tetrahydro-2H-fluorenes **1.157** by alkenylation of a benzylic methyl group.<sup>[88]</sup>

**Scheme 1.21:** Synthesis of 5-membered rings by cyclization of carbamoyl chlorides or alkenyl(pseudo-)halides.

#### 1.2.2.1 Application in the total synthesis of natural products

Although the synthetic relevance of newly described arylation/alkenylation methodologies has been demonstrated by disclosing concise syntheses of natural products, active ingredients or core structures thereof,<sup>[87–91]</sup> significant efforts towards total syntheses of natural products featuring a Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation key step to form small rings were made by the Baudoin group.

As a part of the newly reported methodology for the formation of hexahydroindoles **1.160** from alkenylbromide precursors of type **1.159**, the core structure of aeruginosins (**1.161**) was constructed in 2 additional steps.<sup>[92]</sup> Aeruginosins (**1.170**) are marine natural products that have shown *in vitro* inhibition of serine proteases.<sup>[93]</sup> Their structure consists of a 2-carboxy-6-hydroxyoctahydroindole (Choi) and hydroxyphenyllactic (Hpla) subunits (Scheme 1.23a). Motivated by these results, two congeners of this family of natural products were prepared a few years later.<sup>[94]</sup> The synthesis of the Choi fragment began with alcohol **1.162** from which the alkenyl bromide substrate **1.159a** was prepared in 6 steps. Pd(0)-catalyzed C(sp<sup>3</sup>)-H alkenylation using Pd(Cy<sub>3</sub>)<sub>2</sub> furnished hexahydroindole **1.160a** in gram-scale with yields ranging between 68-71%. Hydrogenation and further functional group transformations led to the Choi fragment in 1.2 g with a yield of 15% over 9 steps. For the Hpla fragment they applied a Pd(II)-catalyzed intermolecular C(sp<sup>3</sup>)-H arylation method reported by the Daugulis group.<sup>[95,96]</sup> The substrate **1.165** for the intermolecular arylation reaction was obtained from **1.164** by benzyl protection, hydrolysis to the acid and installation of the 2-(pyridine-2-yl)isopropyl (PIP) amine directing group. Subjecting **1.165** to Pd(OAc)<sub>2</sub> with aryl iodide **1.166** in presence of K<sub>2</sub>CO<sub>3</sub> led to the formation of **1.167** without racemization of the labile stereogenic center. Removal of the directing group and amide coupling gave fragments **1.168a** and **1.168b** bearing a D-allo-Ile-OMe and D-Leu-OMe hydrophobic amino acid respectively in high yields (Scheme 1.23b).

**Scheme 1.23:** a Pd(0)-catalyzed C(sp<sup>3</sup>)-H alkenylation to form hexahydroindoles **1.160**. b. Syntheses of Choi and Hpla cores of aeruginosins.

The two fragments were then combined by hydrolysis of the methyl ester on the Hpla fragment followed by peptide coupling to give intermediates **1.169a** and **1.169b** (Scheme 1.24).

**Scheme 1.24:** Coupling of Choi and Hpla fragments and installation of C-termini.

Finally, installation of the c-terminus and global deprotection gave the natural products aeruginosin 98B (**1.170a**) and 298A (**1.170b**) in 5.1% and 8.2% overall yield respectively. Later, other members of the same family with halogen substituents on the aromatic ring were reported by the same group.<sup>[97]</sup>

Another major application of Pd(0)-catalyzed C(sp<sup>3</sup>)-H alkenylation was the divergent total synthesis of dithiodiketopiperazine (DTP) natural products (–)-epiccoccin G (**1.176**) and (–)-rostratin A (**1.177**) very recently disclosed by the Baudoin group (Scheme 2.25).<sup>[98,99]</sup> Starting from cheap and abundant cyclohexenone (**1.171**), enantioselective organocatalyzed epoxidation reported by the List group<sup>[100,101]</sup> gave **1.172** in 97:3 e.r. Subsequent triflation followed by regioselective and stereospecific epoxide opening with alanine-*t*Bu ester and acetylation gave intermediate **1.173**. The free acid derivative of **1.173** obtained by deprotection of the *t*Bu group was recrystallized to further improve the d.r. to >99:1 and was then dimerized furnishing dialkenyl triflate **1.174** in decagram scale. The key two-fold C(sp<sup>3</sup>)-H alkenylation was performed by subjecting **1.174** to 4 mol% of Pd(PCy<sub>3</sub>)<sub>2</sub> catalyst. The addition of 20 mol% of free PCy<sub>3</sub> proved essential to avoid mixtures of substrate **1.174**, mono-cyclized product and detriflated byproducts. Overall, the common intermediate **1.175** could be prepared in 51% yield over 7 steps in multigram scale. A 7 step sequence including the oxidation of the double bonds, the introduction of sulfur substituents on the diketopiperazine core and deprotections led to (–)-epiccoccin G (**1.176**) in 19.6% over 14 steps in the longest linear sequence which is a major improvement compared to the first synthesis (1.5% over 15 steps).<sup>[102,103]</sup> For (–)-rostratin A (**1.177**) 3 additional steps from common intermediate **1.175** were required due to the highly challenging installation of the *trans,trans* ring junction. Nevertheless, the first total synthesis of (–)-rostratin A (**1.177**) was completed in 12.7% yield over the longest linear sequence of 17 steps (Scheme 1.25). Moreover, the high efficiency of the presented route allowed the synthesis of the natural products and derivatives in significant amounts which allowed for cytotoxicity assessments of these structures in the leukemia cell line K562.

**Scheme 1.25:** Total synthesis of DTP natural products (–)-epiccoccin G (**1.176**) and (–)-rostratin A (**1.177**) enabled by key two-fold Pd(0)-catalyzed C(sp<sup>3</sup>)-H alkenylation.

In general, Pd(0)-catalyzed C(sp<sup>3</sup>)-H enables the access to of 4-, 5-, 6- and 7-membered hetero- or carbocycles with 5-membered examples being by far the most studied (for an example of 7-membered ring formation see chapter 2,

section 2.1.1). The activation of methyl groups is predominant with a few examples of methylene C–H bond activation, mainly attributed to higher steric encumbrance and reduced acidity of the C–H bond. Electrophiles such as alkenyl(pseudo-) halides, carbamoyl chlorides and imidoyl chlorides are compatible with the reaction giving access to non-aromatic products. Moreover, enantioselective versions, which are of high interest for the pharmaceutical and medicinal industry were developed (see chapter 2, section 2.1). Finally, a wide range of active ingredients and natural products were accessed by Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation strategies further underlining the importance of this method in synthetic organic chemistry.

## Chapter 2: Palladium(0)-catalyzed enantioselective intramolecular arylation of enantiotopic secondary C–H bonds for the synthesis of chiral indanes

### 2.1 Introduction: Pd(0)-catalyzed enantioselective activation of C(sp<sup>3</sup>)–H bonds

The three-dimensional shape of organic molecules is of fundamental importance as it is directly linked to their activity in biological systems.<sup>[104,105]</sup> Therefore, enantioselective transformations have been a field of constant and intensive research and in particular transition metal catalysis has been key to develop improved and more efficient methods.<sup>[106–110]</sup> In this regard, enantioselective Pd-catalyzed C(sp<sup>3</sup>)–H activation has attracted great interest from the synthetic community.<sup>[111–113]</sup> For the Pd<sup>0</sup>–Pd<sup>II</sup> manifold three main strategies have been established over the past decades.<sup>[112]</sup> (1) The *desymmetrization of enantiotopic alkyl groups* relies on the differentiation of two identical alkyl groups on substrates such as **2.1** by the chiral catalyst. In this case, the stereogenic center is formed remote to the activated C–H bond on product **2.2** (Scheme 2.1a). (2) The *activation of enantiotopic 2<sup>ary</sup> C–H bonds* of structure **2.3** leads to chiral product **2.4**. The stereogenic center is formed on the same carbon atom of the C–H activation site (Scheme 2.1b). Because of unfavorable stereoelectronic properties, this enantioselective C(sp<sup>3</sup>)–H activation process represents an important challenge. (3) The third strategy is *kinetic resolution*. Starting from a racemic mixture of **2.5** chiral product **2.6** and enriched starting material **2.7** is obtained performing a classic kinetic resolution, whereas two different enriched products **2.8** and **2.9** are obtained by parallel kinetic resolution (Scheme 2.1c).

**Scheme 2.1:** Strategies for asymmetric Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation. a. Desymmetrization of enantiotopic alkyl groups. b. Activation of enantiotopic 2<sup>ary</sup> C–H bonds. c. Kinetic resolution.

#### 2.1.1 Activation of methyl and methylene C–H bonds

The very first example of Pd(0)/Pd(II)-catalyzed enantioselective intramolecular C(sp<sup>3</sup>)–H activation was reported by Kündig in 2011<sup>[114]</sup> for the synthesis of indolines **2.10** (Scheme 2.2). The activation of secondary C–H bonds was achieved in high yields and enantioselectivities employing chiral *N*-Heterocyclic carbene (NHC) ligands **L2.1**, reported by the same group shortly before.<sup>[115–117]</sup> Later, in addition to expanding the scope to primary C–H bonds, DFT calculations were performed to elucidate the mode of enantioinduction.<sup>[118]</sup> It was found that the reaction proceeds over a concerted metalation deprotonation mechanism which is also the rate-limiting step with

an achiral NHC ligand. However, when a bulky chiral NHC ligand was used, the ligand exchange (bromide for pivalate) was rate-limiting. This change in rate-limiting step is probably attributed to high steric congestion increasing the ligand exchange barrier. Additionally, the *ortho* methyl group in ligand **L2.1a** was essential for high enantioinduction. A study on parallel kinetic resolution was presented from the same group shortly after.<sup>[119,120]</sup> Starting from a racemic mixture of substrate **2.11** two different products **2.12** and **2.13** were obtained. Using ligands **L2.1b** or *ent*-**L2.1a** up to 49% yield for both products and enantioselectivities of 99:1 and 98:2 respectively were achieved.

**Scheme 2.2:** Pioneering studies on enantioselective C(sp<sup>3</sup>)–H activation for the synthesis of indolines.

At the same time of Kündigs first report, Kagan<sup>[121]</sup> and Cramer<sup>[122,123]</sup> disclosed enantioselective methodologies for the activation of C(sp<sup>3</sup>)–H bonds. A limited scope of indoline structures **2.13** was presented by Kagan employing commercially available diphosphine ligand DuPhos. The more complete study on indolines **2.14** by Cramer included the activation of secondary C–H bonds in high yields and enantioselectivities, using chiral monodentate phosphine ligand **L2.2** designed for this methodology. Interestingly, with chiral trialkyl phosphine ligand **L2.3**, which shows comparable electronic properties to PCy<sub>3</sub>, indoline **2.15** was prepared with 96% yield and 85.5:14.5 e.r. (Scheme 2.3).<sup>[123]</sup>

**Scheme 2.3:** Follow-up indoline syntheses by Kagan and Cramer.

Similarly, the Baudoin group disclosed the synthesis of chiral indanes **2.16** via the desymmetrization of enantiotopic methyl groups (Scheme 2.4). Using chiral monodentate binaphthyl ligands of type **L2.4**, originally designed for asymmetric hydrogenations,<sup>[124]</sup> high yields and enantioselectivities were observed.<sup>[125]</sup> In 2015 a more thorough study was published including the activation of secondary C–H bonds leading to indolines **2.17**, where up to three adjacent stereogenic centers are controlled at the same time with high level of diastereocontrol. Three different ligands were used for the substrate scope. Ferrocenyl-substituted **L2.4b** was the most effective for methyl activation whereas for methylene activation *o*-tolyl-substituted **L2.4c** showed the highest reactivity. Finally, ligand **L2.4d** with a 9-methylfluorenyl substituent a pyridine-based substrate could be converted to the indane product. DFT computations showed that London dispersion forces between substrate and ligand are important to stabilize the transition state.<sup>[126]</sup>

**Scheme 2.4:** Synthesis of chiral indanes using monodentate binepine ligands.

Besides chiral ligands, active bases can be used to induce chirality in Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation. For the synthesis of chiral indolines<sup>[122]</sup> (see Scheme 2.3) the Cramer group hypothesized that the active base relays the chiral space created by the ligand to the substrate. Indeed, a matched effect was observed when chiral base (*S*)-**A1** was used in presence of a Pd(0) catalyst and ligand **L2.2a** leading to the formation of chiral indoline (*2R,3S*)-**2.14a** in 75% yield and 82:18 e.r. In the mismatched combination, with chiral base (*R*)-**A1**, diastereoisomer (*2S,3R*)-**2.14a** was obtained with a lower 71:29 e.r. Additionally, the same substrate was subjected to reaction conditions with an achiral IPr and chiral base **A2** resulting in moderate 71:29 enantiomeric ratio (Scheme 2.5a). This result further underlined the ability of chiral bases to induce enantioselectivity. In 2017, the Baudoin group reported the synthesis of chiral indolines **2.19** using chiral phosphoric acid **A3** via desymmetrization of enantiotopic methyl groups and 27 examples were reported with high yields and enantioselectivities (Scheme 2.5b).<sup>[127]</sup> However, in the case of the less reactive methylene C-H bonds a significant decrease in reactivity was observed albeit with consistent high enantioselectivities. Kinetic resolution from rac-**2.20** featuring competing methyl and methylene groups resulted in the formation of product **2.19a** by methyl C-H activation exclusively. In contrast to the report of Kündig, product **2.19b** arising from methylene C-H bond activation was not observed.

**Scheme 2.5:** Chiral active base approach to induce chirality for the formation of indolines.

The enantioselective Pd(0)-catalyzed C–H activation reaction is a powerful tool for the synthesis of biologically active molecules. The first total synthesis of natural products including a Pd(0)-catalyzed enantioselective C(sp<sup>3</sup>)–H activation as key step was reported by the Baudoin group in 2019 (Scheme 2.6).<sup>[128,129]</sup> The norilludalane sesquiterpene natural products (*S*)-puraquinoic (**2.25**) acid, (*S*)-deliquinone (**2.26**) and (*S*)-russujaponol F (**2.27**) share a bicyclic core with a characteristic quaternary stereogenic center. The formation of such quaternary stereogenic centers is a major challenge in synthetic organic chemistry mainly attributed to the build-up of high steric bulk in the transition state.<sup>[130–132]</sup> The C–H activation precursor **2.22** was obtained in seven steps from commercially available 2,5-dimethyl phenol **2.21**. Under the conditions reported by Kündig with the Hermann-type NHC ligand **L2.1a** (see Scheme 2.2) indane product **2.23** was obtained in 87% yield and 85:15 d.r. The proline-derived auxiliary on **2.22** with an isopropyl ester was essential to enhance selectivity as with the methyl ester derivative of **2.22** a significantly lower 66:34 e.r. was observed. Acidic removal of the auxiliary with concomitant deprotection of the methoxide led to indane **2.24**, whose enantiomeric ratio was further improved by recrystallization. Common intermediate **2.25** was prepared in two additional steps from which the three natural products **2.26**, **2.27** and **2.28** could be accessed in 14 to 15 overall steps for the longest linear sequence.

**Scheme 2.6:** Total synthesis of (*S*)-puraquinoic (**2.25**) acid, (*S*)-deliquinone (**2.26**) and (*S*)-russujaponol F (**2.27**) by enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation.

The enantioselective Pd(0)-catalyzed activation of cyclopropyl C–H bonds has gained great interest. The C–H bonds in cyclopropyl rings adopt a more sp<sup>2</sup>-like character because the pronounced ring strain leads to the overlap of the C–H p-orbitals.<sup>[133–135]</sup> Thus, the C–H activation process is more facile compared to linear methylene or methyl C–H bonds. In 2012 the Cramer group reported the use of taddol derived phosphoramidite ligand **L1.2e** for the synthesis of tetraisoquinolines **2.29** in high yields and enantioselectivities (Scheme 2.7).<sup>[123]</sup> Interestingly, when R<sup>2</sup> = H, this methine position was activated preferentially leading to the racemic spiro-fused indoline product. Later the scope was expanded to the synthesis of dihydroquinolones and dihydroisoquinolones **2.30** and **2.31**, respectively employing the same phosphoramidite ligand **L1.2e**.<sup>[136]</sup>

**Scheme 2.7:** Synthesis of tetrahydroisoquinolines **2.29**, dihydroquinolones **2.30** and dihydroisoquinolones **2.31** and application in the synthesis of the core structure of BMS-791325 (**2.34**).

The utility of this method was demonstrated in the synthesis of **2.33** in 73% yield and 92.5:7.5 e.r. representing the major carbon framework of BMS-791325 (**2.34**), a hepatitis C virus NS5B replicase inhibitor featuring a highly functionalized 7-membered ring.<sup>[137]</sup> The selectivity could be further increased using more electron-donating phosphonite ligand **L2.5a**.

In a similar reaction the Charette group observed enantioinduction when using hemilabile phosphine oxide ligand BozPhos for the synthesis of cyclopropane-fused azacycle **2.35** (Scheme 2.8). In this case, the palladium source played an important role.<sup>[138]</sup> With Pd<sub>2</sub>dba<sub>3</sub>, product **2.35** was obtained in 37% yield and 94:6 e.r. whereas with Pd(OAc)<sub>2</sub> the yield could be improved to 87% but the e.r. dropped to of 70:30. Later, the same group reported a more thorough study on the enantioselective activation of cyclopropanes to access dihydroquinolones **2.36** and dihydroisoquinolones **2.37** similar to the reports of the Cramer group (see Scheme 2.7). Using BozPhos as the ancillary ligand up to 99% yield and 99:1 e.r. was obtained.<sup>[139]</sup>

**Scheme 2.8:** Enantioselective activation of cyclopropane C–H bonds with chiral P,O ligand BozPhos.

Different electrophiles were used for the intramolecular C–H activation of cyclopropanes. Cyclopropyl-fused  $\gamma$ -lactams **2.69** were prepared from chloroacetamides **2.38**.<sup>[140]</sup> In this case high enantioselectivities were observed using taddol-derived phosphonite ligand **L2.5b** at relatively mild conditions (Scheme 2.9a). However, when R<sup>2</sup> = H, only starting material was recovered. The same group reported the synthesis of pyrrolidinones **2.41** from imidoyl chlorides **2.40** bearing a perfluorinated alkyl substituent in  $\alpha$ -position to the nitrogen atom (Scheme 2.9b).<sup>[141]</sup> Previously employed phosphoramidite and phosphonite ligands of type **L1.2** and **L2.5** respectively failed to provide sufficient reactivity and enantioselectivity. Instead, chiral alkoxy diazaphospholidine (**R,R**)-**L1.5**,<sup>[142]</sup> with a backbone reminiscent of the NHC ligands **L2.1** described by the Kündig group (see Scheme 2.2), led to the

formation of products **2.41** in excellent yields and enantioselectivities. A variety of postfunctionalizations of the pyrrolidine products were presented including a one-pot procedure for the formation of product **2.41** with subsequent nucleophilic attack on the imine moiety.

**Scheme 2.9:** Enantioselective activation of cyclopropane C–H bonds from chloroacetamides **2.38** and imidoyl chlorides **2.40**. a. Synthesis  $\gamma$ -lactams. b. Synthesis of pyrrolidines.

The above-described methods mainly rely on the desymmetrization of methylene or methyl groups. Consequentially, the stereogenic center is formed in remote to the C–H bond undergoing activation. Examples of enantiotopic C(sp<sup>3</sup>)–H bond activation, where the stereogenic center is formed on the carbon of the activated C–H bond are rare. The only precedent was reported by the Cramer group in 2014.<sup>[143]</sup>  $\beta$ -Lactams **2.42** were prepared from chloroacetamide precursors **2.43** in excellent yields and enantioselectivities using taddol derived phosphoramidite ligand **L1.2f** (Scheme 2.10). Chloroacetamides are prone to substitution reactions. Thus, one of the major challenges of this protocol was to suppress substitution reactions with nucleophilic reagents in the system such as the ligand and the active base. This limitation was overcome using a less nucleophilic phosphoramidite ligand compared to phosphines and more sterically demanding AdCO<sub>2</sub>H as the active base. Additionally, a competition experiment was performed with substrate **2.43a** containing an electron-rich *p*-OMe-substituted phenyl ring electron-deficient *p*-CN-substituted phenyl ring. A product ratio of 4.8:1 in favour of structure **2.42a** arising from the activation of the more acidic benzylic position was observed.

**Scheme 2.10:** Synthesis of  $\beta$ -lactams by activation of enantiotopic C–H bonds.

## 2.2 Enantioselective Pd(0)-catalyzed intramolecular activation of methylene C–H bonds

The development of enantioselective transition metal catalyzed C–H functionalization is a long-standing challenge as it enables easy access to scalemic intermediates from readily available precursors.<sup>[111,144]</sup> The functionalization of non-activated enantiotopic methylene C(sp<sup>3</sup>)–H bonds remains underexplored mainly due to the high bond dissociation energy of 90–110 kcal mol<sup>–1</sup> and accessibility because of steric hindrance. To date, the enantioselective synthesis of  $\beta$ -lactams reported by the Cramer group, is the only precedent (see section 2.1.1, Scheme 2.10). However, this type of C–H bonds is easier to abstract compared to pure secondary aliphatic bonds due to the increased acidity arising from mesomeric stabilization. In this doctoral thesis we describe the development and optimization of an extremely reactive Pd(0)/NHC catalytic system, which is capable of activating secondary enantiotopic C(sp<sup>3</sup>)–H bonds for the formation of chiral indanes. This is a rare example of enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)–H bond activation where the stereogenic center is formed on the C–H activation site.

### 2.2.1 Optimization of reaction conditions

We envisioned to use substrates of type **2.44** where the modular design allows for easy exchange of the aromatic part and the alkyl chain undergoing C(sp<sup>3</sup>)–H activation by sequential alkylation of a malonic ester. In addition, the bulkiness of the malonic esters can tune the Thorpe-Ingold effect required for the ring contraction facilitating cyclization to product **2.45** (see experimental part for substrate synthesis). We chose substrate **2.44a** featuring a fluorine atom para to the alkyl chain to monitor the reaction by <sup>19</sup>F NMR spectroscopy. An initial screening of achiral ligand classes under reported conditions for C(sp<sup>3</sup>)–H activation was performed. Mainly dehalogenated byproduct **2.45** was observed with trialkyl and triaryl phosphine ligands under the conditions described by Ohno<sup>[79]</sup> for the synthesis of indolines (Table 1, entries 1–4). This observation indicates that the putative Pd(II) intermediate does not undergo C–H activation. Consequentially, more strongly  $\sigma$ -donating NHC<sup>[145]</sup> and cyclic alkyl amino carbene (CAAC)<sup>[146]</sup> ligands, that form more stable and electron-rich metal catalysts, were tested. Only starting material **2.44a** or protodehalogenation was observed under the conditions described by the Kündig group<sup>[114]</sup> with classic NHC ligands IAd, IMes and IPr (entries 5–7). In the case of CAAC ligand **L2.6** almost no conversion occurred, presumably due to its higher degree of saturation compared to the other NHC ligands, thus leading to decomposition under elevated temperatures.<sup>[114]</sup> Substantial product formation was obtained with IBiox-type ligands developed by the Glorius group.<sup>[147]</sup> With IBioxMe<sub>4</sub> and IBiox6 30% and 73% of the desired product was observed respectively (entries 9 and 10).

**Table 2.1:** Screening of achiral ligands.

<sup>a</sup>Determined by <sup>19</sup>F-NMR

Encouraged by these initial results, we turned our attention to chiral ligands. Binepine ligand **L2.4b** failed to provide any product formation in this case. Instead, Krapcho-type decarboxylation was observed as only side product (Table 2, entry 1). Phosphoramidite **L1.2b** and Phosphinite **L2.5c** were also not suitable ligands (entries 2 and 3). Surprisingly, no traces of product **2.45a** were observed with NHC ligand **L2.1a** (entry 4). Chiral IBiox ligands IBioxMenth and IBiox*t*Bu gave product **2.45** with 41% and 33% product formation and high to excellent 86:14 and 99:1 e.r. respectively (entries 5 and 6).

**Table 2.2:** Screening of chiral ligands.

These results prompted us to prepare chiral congeners of the same IBioxR ligand family and examine them in our reaction. Identical results were obtained with IBiox*i*Pr and IBioxCy, with 13% of product **2.45a** along with 37% of proto-dehalogenated byproduct **2.46a** (Table 2.3, entries 1 and 2). In the case of IBiox*i*Bu very poor reactivity was observed leading mainly to recovery of starting material **2.44a** (entry 3). A 1:1 ratio of product **2.45a** and byproduct **2.46a** were formed with IBioxAd as ligand (entry 4). The e.r. of 95:5 was comparable to the one obtained with IBiox*t*Bu (see Table 2.2, entry 6). Further optimization was undertaken with IBioxAd because the best reactivity/enantioselectivity compromise was obtained.

Reaction parameters such as concentration, temperature and base loading were evaluated. Diluting the reaction from 0.1 M to 0.05 M gave 53% of **2.45a** and 98:2 e.r. (Table 2.4, entry 1). Conversely, a higher 0.2 M concentration led to slightly increased product formation of 60% and unchanged 98:2 e.r. (entry 2). At 120 °C only traces of product **2.45a** were observed along with 69% of starting material **2.44a** indicating that higher temperatures are required to achieve full conversion (entry 3). At 140 °C again full conversion was observed with 55% product formation (entry 4). Combining a concentration of 0.2 M with a lower temperature of 140 °C slightly increased the product formation to 59% (entry 5). At 160 °C a marginal increase in product formation to 60% and 63% was obtained with 2.0 or 3.0 equiv of Cs<sub>2</sub>CO<sub>3</sub> loading (entries 6 and 7). With 2.0 equiv of Cs<sub>2</sub>CO<sub>3</sub> at 140 °C resulted in lower product formation of 49% (entry 8).

**Table 2.4:** Effect of concentration, temperature and amount of stoichiometric base Cs<sub>2</sub>CO<sub>3</sub> on the product formation.

Solvent and base screenings were conducted at a 0.1 M concentration. The active base screening with 1.5 or 2.0 equiv Cs<sub>2</sub>CO<sub>3</sub> at either 140 °C or 160 °C showed that pivalate derivatives were the most effective (Table 2.5, entries 1-6). Since the free pivalic acid and its cesium salt performed similarly giving 65% product formation, we decided to continue our study with CsOPiv for practicality reasons. Changing mesitylene for the more polar *n*-dibutyl ether solvent did not have any positive effect (entry 7). In xylenes, product **2.45a** was obtained with comparable product formation of 62%. (entry 8). In presence of 3 Å and 4 Å molecular sieves the product formation dropped significantly to 15% and 36% respectively (entries 9 and 10). Conversely, 5 Å molecular sieves proved to be highly beneficial as indane **2.45a** was formed in 80% together with 18% of proto-dehalogenated byproduct **2.46** (entry 11). Different active base loading did not give improved results (entries 12 and 13). Performing the reaction in isolated isomers *o*- and *p*-xylenes was not fruitful either (entries 14 and 15).

**Table 2.5:** Influence of active base, amount of stoichiometric base Cs<sub>2</sub>CO<sub>3</sub>, temperature and solvent on the formation of product **2.45a**.

<sup>a</sup>Determined by <sup>19</sup>F-NMR. <sup>b</sup>Determined by HPLC on a chiral stationary phase. <sup>c</sup>n.d. = not determined

Precatalysts Pd( $\pi$ -allyl)Cp and Pd( $\pi$ -cin)Cp led to poor product formation of 15% and 26% respectively (Table 2.6, entries 1 and 2). A similar reactivity was observed with [Pd( $\pi$ -allyl)Cl]<sub>2</sub> giving 79% of indane **2.45a**. This precatalyst was chosen for further studies due to its straightforward preparation with high purity, thus preventing reproducibility issues.

With no major improvement after the screening of palladium sources we turned back to the active and stoichiometric bases. Keeping Cs<sub>2</sub>CO<sub>3</sub> as the base, with xanthoic acid, dibenzyl phosphonate, PivNHOH only traces of product **2.45a** were observed (Table 2.7, entries 1-3).

**Table 2.7:** Second screening of active and stoichiometric base.

Entry	active base	base	Product ratio <sup>a</sup>			
			2.45a	2.46a	2.44a	others
1	xanthoic acid	Cs <sub>2</sub> CO <sub>3</sub>	-	11	87	2
2	dibenzyl phosphate	Cs <sub>2</sub> CO <sub>3</sub>	3	8	88	1
3	PivNHOH	Cs <sub>2</sub> CO <sub>3</sub>	4	14	66	16
4	hexanoic acid	Cs <sub>2</sub> CO <sub>3</sub>	61	30	2	7
5	AdCO <sub>2</sub> H	Cs <sub>2</sub> CO <sub>3</sub>	5	3	91	1
6	MesCO <sub>2</sub> H	Cs <sub>2</sub> CO <sub>3</sub>	14	14	67	5
7	AcOH	Cs <sub>2</sub> CO <sub>3</sub>	1	8	88	3
8	CsOPiv	K <sub>2</sub> CO <sub>3</sub>	4	17	35	44
9	CsOPiv	Rb <sub>2</sub> CO <sub>3</sub>	35	18	-	47
10	CsOPiv	K <sub>3</sub> PO <sub>4</sub>	12	18	45	25
11	CsOPiv	CsOH	3	32	57	8

<sup>a</sup>Determined by <sup>19</sup>F-NMR.

With hexanoic acid a significant product formation of 61% was observed however, still not outperforming CsOPiv (entry 4). Retesting AdCO<sub>2</sub>H, MesCO<sub>2</sub>H and AcOH under the new conditions was not beneficial (entries 5-7). The size of the counter ion of different carbonate sources played an important role, as with the smaller K<sup>+</sup> and Rb<sup>+</sup> (compared to Cs<sup>+</sup>) a significant lower product formation of 4% and 35% respectively was observed (entries 8 and 9). Presumably, this behaviour is attributed to increased solubility of the carbonate as the larger counter ion dissociates more easily. With K<sub>3</sub>PO<sub>4</sub> only traces of indane **2.45a** were observed (entry 10). Similarly, with CsOH only 3% of the product was formed. Unfortunately, in this optimizations no increase in product formation was observed and therefore the e.r. values were not recorded.

We reevaluated the solvent effect under the new reaction conditions. With etheric solvents CPME, 1,4-dioxane and *n*Bu<sub>2</sub>O, no improvement compared to xylenes was made (Table 2.8, entries 1-3). With *t*-Amyl alcohol as the reaction medium no product was observed (entry 4). Aromatic solvents such as pseudocumene, cumene and *p*-cymene, led to significant lower product formation (entries 6-7). In toluene, 76% of **2.45a** was obtained (entry 8).  $\alpha,\alpha,\alpha$ -Trifluorotoluene outperformed xylenes giving a product formation of 84% and 98:2 e.r. (entry 9). This result could be further improved to 95% together with only traces of dehalogenated byproduct **2.46a** using freshly distilled and degassed solvent (entry 10). The 98:2 enantiomeric ratio remained stable.

**Table 2.8:** Screening of solvents.

The chiral IBioxR ligands were revisited in  $\alpha,\alpha,\alpha$ -trifluorotoluene. IBioxMenth•HOTf gave product **2.45a** in high 89% isolated yield albeit in low 14:86 e.r. (Table 2.9, entry 1). IBiox*i*Pr•HOTf led to 14% yield and a similar 85:15 e.r. (entry 2). Slightly higher e.r. was observed with IBioxCy•HOTf despite a moderate 39% yield (entry 3). Finally, IBiox*t*Bu•HOTf and IBioxAd•HOTf performed similarly giving indane product in 88% and 91% yield respectively and 98:2 e.r. (entries 4 and 5).

**Table 2.9:** Screening of IBioxR ligands under optimized conditions.

### 2.2.2 Scope of the Pd(0)-catalyzed asymmetric synthesis of indanes

The reaction scope was investigated under the finalized conditions. Precursors **2.44b-e** with aliphatic chains varying in length and steric bulk were suitable substrates giving indane products **2.45b-e** in good to high yields and high enantioselectivities (Scheme 2.11). Additionally, product **2.45c** could be prepared from both the corresponding aryl bromide and aryl chloride precursor, demonstrating the compatibility of the protocol with more economical and readily available aryl chlorides. Alkyl chains with a terminal fluorine atom (**2.45f**) and functional groups such as esters (**2.45g**), protected alcohols (**2.45h**, **2.45i**) and protected amides (**2.45j**) were well tolerated. To demonstrate the robustness of the method, product **2.45j** was prepared in a 2.0 mmol scale in slightly lower 63% yield but high >99:1 e.r. after recrystallization. The malonic ester moiety plays a fundamental role for the cyclization of the products as it induces a Thorpe-Ingold effect that contracts the bond angle bringing the targeted C–H bond closer to the Pd-catalyst.<sup>[148]</sup> More sterically demanding ethyl and isopropyl esters were employed (**2.45k**, **2.45l**). The latter was obtained with moderate 34% isolated yield due to the difficult separation from the protodehalogenated byproduct. Products with fluorine substituents *meta* or *para* to the newly formed C–C bond were obtained in high yields and enantioselectivity (**2.45m**, **2.45a**). Notably, **2.45a** was prepared with the well-defined [Pd(IBioxAd)( $\pi$ -allyl)Cl] complex in comparable yield and selectivity. Electron withdrawing substituents on the aromatic ring such as NO<sub>2</sub>, CF<sub>3</sub>, CO<sub>2</sub>Me and SO<sub>2</sub>Me were also compatible with the protocol (**2.45n**, **2.45o**, **2.45p**, **2.45q**). Despite the moderate yield, substrate **2.44r** featuring a strongly electron donating 1,3-dioxolan substituent was converted into the product in comparable enantioselectivity. Finally, tricyclic product **2.45s** arising from two-fold C–H activation was prepared by doubling the catalyst loading.

**Scheme 2.11:** Scope of the reaction. <sup>a</sup>After recrystallization. <sup>b</sup>Reaction performed with [Pd(1BioxAd)( $\pi$ -allyl)Cl] complex. <sup>c</sup>Reaction performed in presence of 10 mol% [Pd( $\pi$ -allyl)Cl]<sub>2</sub> and 20 mol% of IBioxAd•HOTf.

Chiral tertiary amides are highly desirable motifs found in natural and synthetic molecules with numerous applications in the pharmaceutical industry.<sup>[149–151]</sup> However, due to its acidic stereogenic center in  $\alpha$ -position of the carbonyl they are very challenging to access. We therefore attempted the synthesis of product **2.45t** by activating the methylene C–H bond in  $\alpha$ -position of a dimethyl amide substituent. Surprisingly, the product was obtained in almost quantitative yield and a high 95:5 e.r. (Table 2.10, entry 1). With substrate **2.44u** bearing a morpholine amide functional group lower yield and a decrease in enantioselectivity to 68:32 e.r. was observed (entry 2). We hypothesized that racemization occurred after the reaction went to full completion and therefore reduced the reaction time from 18 to 8 h. Indeed, enantioselectivity was restored to 97:3 (entry 3). Similarly, product **2.45v** was obtained in 80% yield and 70:30 e.r. (entry 4) after 18 h and reducing the reaction time to 4 h increased the enantioselectivity again to 98:2 e.r. (entry 5). Methyl ester **2.44w** however, gave only racemic product **2.45w** before full completion. This suggests, that the racemization process is faster than the C–H activation reaction. Nevertheless, we prepared three tertiary amides **2.45t–v** by enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)–H bond activation, which, to our knowledge, is the first report of this kind of transformation.

**Table 2.10:** Synthesis of 3<sup>ary</sup> amides.

Entry	Product	R	t [h]	Yield [%] <sup>a</sup>	e.r. <sup>b</sup>

<sup>a</sup>Yield of isolated product. <sup>b</sup>Determined by HPLC on a chiral stationary phase. <sup>c</sup>n.d. = not determined.

Heteroaromatic substrates were less efficient, displaying low product formation or no reactivity at all. For pyridine derived substrates **2.44x** and **2.44y**, the reaction did not reach full conversion and only a product formation of 55% was observed for both entries (Scheme 2.12). The product could not be separated by column chromatography because the reaction mixture contained substantial amounts of starting aryl bromide and dehalogenated byproduct. In the case of pyrazine- and quinolone- based substrates **2.44z** and **2.44aa** only traces of the product were observed. Presumably, coordination of the nitrogen to Pd led to catalyst sequestration. For thiazole-derived substrates **2.44ab** and **2.44ac** similar results were obtained. High amounts of proto-dehalogenation and starting material were observed, presumably due to the challenging reductive elimination to form the strained 5,5-fused ring system. Substrates featuring strongly electron-donating substituents in *para* and *meta* position to the bromine on the aromatic ring (**2.44ad**, **2.44ae** and **2.44af**) were not efficient leading to mainly proto-dehalogenation. Finally, the modification of the ring-contracting substituents from a malonic ester to a dimethyl ether (**2.44ag**) to tune the Thorpe-Ingold effect had a negative impact on the reaction outcome. Also in this case, mostly proto-dehalogenation together with non-converted starting material was observed.

**Scheme 2.12:** Unsuccessful C–H activation substrates.

To demonstrate the utility of the chiral indanes **2.45** we aimed to derivatize representative examples. Based on recent literature reports converting malonic acids to gem-difluoro and fully decarboxylated derivatives,<sup>[152,153]</sup> we envisaged to prepare products **2.45cb** and **2.45cc** (Scheme 2.13a). However, subjecting starting material **2.45ca**, which was obtained from racemic **2.45c** by saponification, to Ag-catalyzed gem-difluorination conditions was unsuccessful. Similarly, product **2.45cc** was not observed under photoinduced decarboxylation conditions. These results prompted us to select substrate **2.45j** featuring a heavy phthalimide functional group and change our functionalization strategies (Scheme 2.12b). Deprotection of the phthalimide moiety with hydrazine hydrate and concomitant cyclization led to *cis*-configured tricyclic structure **2.45ja** in very high yield and as single observable diastereoisomer. Additionally, spirocyclic dimethyl-barbiturate derivative **2.45jb** was prepared from **2.45j** by condensation with urea and subsequent methylation.

**Scheme 2.13:** Derivatizations of indane products **2.45**.

Efforts to grow crystals suitable for X-ray analysis were unsuccessful. Therefore, the stereogenic center was determined to have the *R* configuration based on the vibrational circular dichroism (VCD) spectroscopy analysis of products **2.45c**, **2.45t** and **2.45ja** performed in collaboration with Prof. Dr. Thomas Bürgi (see experimental section for further details).

In order to determine the kinetic isotope effect (KIE) protiated **2.44ah** and deuterated **2.44ah-d5** were prepared and parallel kinetic experiments were performed using the well-defined [Pd(1*Bio*xtBu)( $\pi$ -allyl)Cl] complex. The observed induction period is attributed to the reduction of the Pd(II) precatalyst to the Pd(0) active species<sup>[154]</sup> and therefore an exact value could not be determined. Nevertheless, a clear isotope effect is visible as the reaction profile for protiated **2.44ah** (deep blue curve) is steeper than the one of deuterated **2.44ah-d5** (deep red curve). This result suggests that the C–H activation step is rate-limiting.

**Figure 2.1:** Parallel KIE experiments with **2.45ah** and **2.45ah-d<sub>5</sub>**.

### 2.2.3 Evaluation of steric properties of IBioxR ligands

In parallel to this study, investigations on new modifications of IBiox-type ligands were ongoing in our group. IBioxMe<sub>4</sub>tBu was designed and prepared by introducing methyl groups in α-position of the oxygen in the bioxazoline scaffold in collaboration with Diana Cavalli. This would bring the substituents on the stereogenic centers closer to each other leading to a tighter chiral space enhancing the enantioinduction. Satisfyingly, using IBioxMe<sub>4</sub>tBu under our optimized conditions led to product **2.45a** in almost enantiopure form although in slightly lower 78% yield (Scheme 2.14). Additionally, we could improve the e.r. of product **2.45n**, with the lowest e.r. in the scope, from 94:6 to 98.5:1.5 with the newly synthesized ligand.

**Scheme 2.14:** Influence of gem-dimethyl substitution on the bioxazoline scaffold of IBioxMe<sub>4</sub>tBu on the enantioinduction.

We studied the correlation between enantioinduction and the structure of the ligand. A typical model to describe sterics for NHC ligands is the percentage of buried volume (% *V*<sub>Bur</sub>), originally presented by Nolan and Cavallo.<sup>[155]</sup> The % *V*<sub>Bur</sub> value is defined as the percentage of the total volume of a sphere occupied by the ligand. The metal center is thereby positioned at the core of the sphere with a defined radius *r* (Figure 2.2a). The potential coordination sphere of the metal is represented by the volume of the sphere. We calculated the % *V*<sub>Bur</sub> values of IBioxAd, IBioxtBu, IBiox*i*Pr, IBioxCy, IBioxMenth and IBioxMe<sub>4</sub>tBu entering the parameters of the [Pd(NHC)(π-allyl)Cl] complexes obtained by DFT structure optimization in the sambVca (Salerno molecular buried volume calculation) online tool (Figure 2.2b).<sup>[156]</sup>

**Figure 2.2:** a. Schematic representation of %  $V_{Bur}$ . b. Heat maps of the IBioxR-type NHC ligands and their %  $V_{Bur}$ /%  $V_{Bur(QD)}$  values. %  $V_{Bur(QD)}$  = [%  $V_{Bur}$ (NE quadrant) + %  $V_{Bur}$ (SW quadrant) – %  $V_{Bur}$ (NW quadrant) – %  $V_{Bur}$ (SE quadrant)]/2.

The quadrant difference buried volume (%  $V_{Bur(QD)}$ ) is then obtained by adding the %  $V_{Bur}$  of the more occupied quadrants of the heat map and subtracting the %  $V_{Bur}$  of the less populated quadrants.

No direct correlation between the enantiomeric ratio and the %  $V_{Bur}$  was observed when plotting the enantiomeric ratio as a function of the %  $V_{Bur}$ , (Figure 2.3a). However, the enantiomeric ratio clearly increases with the %  $V_{Bur(QD)}$  (Figure 2.3b). This provides an explanation why the more congested cage-like structure of IBioxMenth is the least effective in terms of enantioinduction compared to the IBioxR ligands featuring a tertiary stereogenic center on the bisoxazoline backbone.

**Figure 2.3:** Study of ligand structure and enantioselectivity. a. %  $V_{Bur}$  as a function of enantioselectivity. b. %  $V_{Bur(QD)}$  as a function of enantioselectivity

## 2.2.4 Application of enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)-H bond activation in total synthesis of natural products

Because chiral indanes are common motives in natural products,<sup>[157]</sup> we thought of demonstrating the utility of our methodology in the total synthesis of prenylated flavonoids indidene A-C (**2.47-2.49**) and Renifolin D-H (**2.50-2.54**) (Scheme 2.15a).<sup>[158,159]</sup> Indidene A-C (**2.47-2.49**) were isolated from the bark of the *Streblus indicus* tree, and exhibit cytotoxic activity against human lung epithelial A549 and human breast adenocarcinoma MCF-7 cell lines with IC<sub>50</sub> values ranging from 2.2 ± 0.1 to 7.2 ± 0.9 μM making them desirable targets for drug development. We envisioned that the synthesis of representative structures indidene A (**2.47**), renifolin D (**2.50**) and indidene C (**2.49**) could be realized in a divergent fashion via common intermediate **2.56** (Scheme 2.15b).

**Scheme 2.152:** Application of enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation of secondary C-H bonds. a. Prenylated flavonoids natural products featuring a chiral indane core. b. Representative retrosynthetic analysis of indidene A (**2.47**), renifolin D (**2.50**) and indidene C (**2.49**).

Weinreb-amide formation followed by nucleophilic addition of Grignard reagent derived from **2.57** would give intermediate **2.55**. Global deprotection would directly lead to the first natural product, indidene A (**2.47**), and further dehydration of the tertiary alcohol would form Renifolin D (**2.50**) featuring an isopropenyl substituent on the 5-membered ring. The biaryl scaffold of indidene C (**2.49**) is envisioned to be constructed by employing a

Pd(II)-catalyzed directed C(sp<sup>2</sup>)-H arylation strategy<sup>[160]</sup> between structure **2.57** and common intermediate **2.56** using the carboxylic acid substituent as traceless directing group. Following deprotection reactions would then grant access to the natural product. Common intermediate **2.56** is traced back to structure **2.58** by attack of the methyl ester with an excess of MeMgBr followed by deprotection of the aliphatic alcohol and oxidation to the corresponding carboxylic acid. *Trans* configured **2.58** would be prepared by krapcho-type monodecarboxylation of **2.45** which in turn is accessed by our developed enantioselective Pd(0)/NHC catalyzed arylation of secondary C(sp<sup>3</sup>)-H bonds. Substrate **2.44** for the enantioselective C-H activation could be prepared from cheap and readily available benzodioxole **2.59** via a sequence of functional group manipulations including lithiation/formylation, reduction to the benzylic alcohol, Appel-type reaction and sequential alkylation of dimethyl malonate.

We started the forward synthesis of natural products indidene A (**2.47**), renifolin D (**2.50**) and indidene C (**2.49**) with commercially available dioxolane **2.59** (Scheme 2.16). Following a literature procedure,<sup>[161]</sup> intermediate **2.60** was obtained over 3 steps in 83% overall yield. Alkylation of methyl malonate at room temperature afforded benzylic malonate **2.61**. Then, alkylation with the desired alkylbromide allowed for the installation of chains bearing protected alcohols in good yields. We selected benzyl (Bn) (**2.44ai**) and *tert*-butyldimethylsilyl (TBS) (**2.44aj**) protecting groups due to their orthogonality to the protected catechol moiety.

**Scheme 2.16:** Synthetic route to model substrates **2.44ai** and **2.44aj** for the enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation.

Subsequently, substrates **2.44ai** and **2.44aj** were subjected to our optimized conditions. The reaction was monitored by GC-MS and 83% of product **2.45ai** was observed along with 12% proto-dehalogenation byproduct **2.46ai** (Table 2.11, entry 1). The product could not be isolated due to difficulties in separation from the proto-dehalogenated byproduct. Nevertheless, the e.r. of the crude mixture could be determined to be 98:2. Less product formation and increased proto-dehalogenation was observed with TBS protected substrate **2.44aj**, presumably due to higher steric hindrance interfering with the C-H activation process (entry 2).

**Table 2.11:** Test of model substrates for the enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation key step of the total synthesis.

Entry	Substrate	PG	Product ratio <sup>a</sup>				e.r. <sup>b</sup>
			2.45	2.46	2.44	others	
1	2.45ai	Bn	83	12	-	5	98:2
2	2.45aj	TBS	62	31	-	7	n.d. <sup>c</sup>

<sup>a</sup>Determined by GC-MS. <sup>b</sup>Determined by HPLC on a chiral stationary phase. <sup>c</sup>n.d. = not determined.

With these preliminary results, the fundament for the total synthesis was layed as it was proven that the key enantioselective C(sp<sup>3</sup>)-H activation occurs in high product formation and excellent enantioselectivity. Efforts to complete the total syntheses are currently ongoing in the group.

## 2.3 Expansion of enantioselective Pd(0)-catalyzed activation of secondary C-H bonds to different substrate families

To explore chemical diversity, we prepared new substrates for our developed enantioselective Pd(0)-catalyzed methodology including sulfonamide **2.62** amide **2.63** and biaryl-based substrates **2.64** and **2.65** (Scheme 2.17). A brief screening under our optimized conditions with achiral ligand IBiox6•HOTf showed that sulfonamide **2.62** and amide **2.63** were not compatible with our protocol as mostly starting material and proto-dehalogenation were observed by GC-MS. With the biaryl substrates the possibility of forming larger 6- or 7-membered rings was interrogated. With **2.64** again no product was observed. Although GC-MS analysis showed the presence of product **2.65** <sup>1</sup>H NMR spectrum of the crude mixture was not insightful and the isolation of the compound for characterization was not successful due to the low amount observed and the presence of the proto-dehalogenated byproduct.

**Scheme 2.17:** Substrate screening for Pd(0)-catalyzed enantioselective activation of secondary C-H bonds.

We turned our attention to the enantioselective synthesis of benzocyclobutenes of type **2.67** from aryl bromides **2.66**. Chiral benzocyclobutenes are highly desirable motifs found in several bioactive and pharmaceutical compounds. In this context, we also thought of targeting the long-standing challenge that is the formation of tertiary stereogenic centers in  $\alpha$ -position to an amide with our substrate design. Moreover, since the first report from the Baudoin group in 2008 on the racemic synthesis of benzocyclobutenes by Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation,<sup>[74,75]</sup> no enantioselective version has been published to date. Thus, structure **2.66a** was subjected to the reported conditions for the formation of benzocyclobutenes by Pd(0) catalysis. With trialkylphosphine ligand *Pr*Bu<sub>3</sub> at 140 °C in the presence of Cs<sub>2</sub>CO<sub>3</sub> in DMF only Krapcho-type monodecarboxylation of the starting material was observed (Table 2.12, entry 1). Using our optimized conditions with achiral NHC ligand IBiox6•HOTf a complex mixture of different products was observed on GC-MS and NMR analysis of the crude mixture was not conclusive (entry 2). We then tested substrate **2.66b** bearing a more acidic C-H bond in  $\alpha$ -position to an ester group. Similarly, with *Pr*Bu<sub>3</sub> decarboxylation of the malonate occurred and with the NHC ligand a complex mixture was obtained.

**Table 2.12:** Screening of conditions for the formation of benzocyclobutenes.

Entry	R	conditions	observation
1	NMe <sub>2</sub>	a	mono decarboxylated <b>2.66a</b>
2	NMe <sub>2</sub>	b	complex mixture of products
3	OMe	a	mono decarboxylated <b>2.66b</b>
4	OMe	b	complex mixture of products

To further expand and establish the synthesis of chiral tertiary amides by Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation, we prepared glycine derived substrates of type **2.68**. Subjecting substrate **2.68a** to our optimized conditions led to recovery of starting material. Based on this result we modified the substrate changing the protecting group from COCF<sub>3</sub> to COAd to increase steric bulk at this position and therefore enhance the Thorpe-Ingold effect. Additionally, we introduced a methyl ester in place of the *t*Bu ester to reduce the steric hindrance, thus making the C-H bond in α-position more accessible for activation. Under the same conditions, with substrate **2.68b** mainly starting material with traces of proto-dehalogenated byproduct **2.70b** was obtained. Changing to a more classical catalytic system with phosphine ligands PCy<sub>3</sub> and PPh<sub>3</sub> was not fruitful either as mainly starting material and other not identifiable byproducts by both GC-MS and NMR spectroscopy, were observed (entries 3 and 4).

**Table 2.13:** Screening of conditions for the formation of indolines.

Entry	Substrate	PG	R	conditions <sup>a</sup>	Product ratio <sup>a</sup>			
					2.69	2.70	2.68	others
1	2.68a	COCF <sub>3</sub>	<i>t</i> Bu	a	-	6	94	-
2	2.68b	COAd	OMe	a	-	2	98	-
3	2.68b	COAd	OMe	b	-	-	78	-
4	2.68b	COAd	OMe	c	-	-	62	38

<sup>a</sup>Determined by GC-MS.

Finally, we engaged sulfonamide **2.71** to our optimized conditions with achiral IBiox6•HOTf. The mass of a C–H activation product, along with not identifiable traces of other byproducts, was observed by GC-MS analysis. NMR analysis of the crude mixture indicated the formation of product **2.72** arising from the activation of the C(sp<sup>2</sup>)–H bond of the aromatic ring on the sulfone (Scheme 2.18).

**Scheme 2.18:** Construction of 8-membered ring (**2.72**) via methyl C(sp<sup>2</sup>)–H activation.

Interestingly, the formation of a thermodynamically unfavored 8-membered palladacycle by activation of the C(sp<sup>2</sup>)–H bond was preferred over the activation of a secondary C(sp<sup>3</sup>)–H bond to form **2.73**. Future efforts will focus on the suppression of this pathway by blocking this position.

## 2.4 Conclusion

The enantioselective synthesis of chiral indanes by Pd(0)-catalyzed arylation of secondary C–H bonds was developed. Key for the realization of this project was the design of an Pd/IBioxR catalytic system which outperformed previously applied phosphine based ligands in the activation of C(sp<sup>3</sup>)–H bonds. The reaction proved to be tolerant to numerous functional groups as a broad variety of chiral indanes were obtained in high yields and enantioselectivities (up to 95% and >99:1 e.r.). Moreover, the first synthesis of chiral 3<sup>ary</sup> amides featuring a labile stereogenic center was achieved by Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation with consistent high enantioselectivities. Additionally, with a steric analysis of IBioxR ligands the correlation between the ligand structure and enantioselectivity could be elucidated. The e.r. does not correlate directly with the % *V*<sub>Bur</sub> however it was found to increase as a function of % *V*<sub>Bur(QD)</sub>. The total synthesis of prenylated chalcones natural products featuring a chiral indane core is envisaged as an application for the developed method. Preliminary results showed that the key enantioselective C(sp<sup>3</sup>)–H activation step in high product formation and consistent high e.r. of 98:2. To date, attempts to expand the protocol to new substrates for the formation of smaller or bigger rings and tertiary stereogenic centers in α-position to carbonyls were unsuccessful.

## Chapter 3: The effect of $\alpha$ -substitution on the reactivity of Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation for the formation of indanes

### 3.1 Introduction

Mechanistic studies are central to the development of synthetic organic chemistry as they allow for the understanding of previously unknown features of reaction mechanisms and can enable rational design for the development of new reactions or the improvement of existing methods. In this context, DFT calculations have been demonstrated to be a powerful computational tool to support such studies in C–H bond activation, providing insights that would otherwise be difficult or impossible to obtain experimentally.<sup>[162]</sup> For the Pd(0)-catalyzed oxidative addition induced C(sp<sup>3</sup>)-H activation important developments towards understanding the operational mechanism have been made over the past two decades. In this context, the Fagnou group reported the synthesis of benzohydrofurans **1.140** from aryl bromide precursors **3.1** (Scheme 3.1).<sup>[78]</sup> With DFT methods the C–H bond insertion pathway proceeding through a Pd(IV) intermediate could be excluded based on the calculated energy of 47.7 kcal mol<sup>-1</sup>. Instead, intramolecular carboxylate assisted transition state **3.3** was found to have a  $\Delta G^\ddagger_{298K}$  value of 27.7 kcal mol<sup>-1</sup> in benzene. The kinetic isotope effect was determined both experimentally and computationally resulting in 5.4 and 3.6 respectively. This is in accordance with the proton abstraction being the rate-limiting step.<sup>[163]</sup> Additionally, during the study of the reaction scope important site-selectivity trends were observed. Methyl groups were preferentially activated over methylene groups (**1.140b** and **1.140c**) however, the formation of a 6-membered ring arising from the activation of the terminal methyl C–H bond on the ethyl substituents was not observed. With a substrate bearing a C(sp<sup>2</sup>)-H bond that could compete in the reaction, this position was favored, forming a 7-membered palladacycle to give structure **3.4** rather than the activation of the methyl C–H bond.

**Scheme 3.1:** Synthesis of benzohydrofurans **1.140** by Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation.

To rationalize the observed site selectivity, the transition states for the activation of the three different C(sp<sup>3</sup>)-H bonds on substrate **3.1b** were calculated (Scheme 3.2). The lowest energy-barrier of 27.0 kcal mol<sup>-1</sup> was obtained for transition state **3.5**, derived from the activation of the methyl C–H bond followed by transition state **3.6** with 32.5 kcal mol<sup>-1</sup> arising from the activation of the methylene C–H bond on the ethyl substituent. The activation of the terminal methyl group C–H bond of the ethyl substituent requires an activation energy of 33.1 kcal mol<sup>-1</sup> further underlining the greater ease with which the activation of the C(sp<sup>2</sup>)-H bond occurs to form product **3.4** over a 7-membered palladacycle.

**Scheme 3.2:** Calculated transition states for the activation C–H bond of the methyl group (**3.5**), methylene C–H bond (**3.6**) and terminal methyl C–H bond (**3.7**) of the ethyl substituent.

In 2008 the Baudoin group disclosed a thorough mechanistic study based on the formation of benzocyclobutenes **1.131** from aryl bromide precursors **3.8** (Scheme 3.3).<sup>[74]</sup> To gain a complete mechanistic picture of the reaction, the authors computationally interrogated the critical mechanistic steps: 1) oxidative addition, 2) C–H bond activation and 3) reductive elimination. It was found that the oxidative addition proceeds through transition state **3.9** with a low activation barrier of 4.7 kcal mol<sup>-1</sup> forming an oxidative addition complex with the aryl substituent in the *trans* position relative to the phosphine ligand. Following ligand exchange with carbonate, proton transfer perpendicular to the Ph–Pd–P plane via CMD transition state **3.10** takes place with an activation barrier of 27.6 kcal mol<sup>-1</sup>. This result is in line with the value obtained by the Fagnou group although the aryl and the ligand were arranged in a *cis* fashion during the transition state in their case (see Scheme 3.1). Finally, reductive elimination was found to proceed through transition state **3.11** lacking the protonated active base, as no minima could be located with the base still coordinated. Although, a high ring strain builds up during the C–C coupling process the calculated energy of 22.5 kcal mol<sup>-1</sup> is lower than for the proton abstraction process. Thus, the C–H activation is rate-limiting, which is supported by a significant primary KIE being observed.

**Scheme 3.3:** Synthesis of benzocyclobutenes **1.131** and computational investigation of oxidative addition, CMD and reductive elimination.

The synthesis of amides **1.142** and sulfonamides **1.143** from substrates of type **3.12** and **3.13** respectively was used by the Fagnou group to further elucidate the mechanism of the Pd(0)-catalyzed C(sp<sup>3</sup>)–H activation by both, experimental and DFT methods (Scheme 3.4).<sup>[80]</sup> For the formation of amides **1.142** an energy barrier of 29.1 kcal mol<sup>-1</sup> was obtained for the proton abstraction via CMD transition state **3.14**. This step was proven to be rate-limiting by the measurement of an intra- and intermolecular KIE of 3.4 and 6.5 respectively, which are in the range of previously disclosed KIE values.

**Scheme 3.4:** a. Synthesis of amides and sulfonamides by intramolecular C(sp<sup>3</sup>)-H arylation. b. Measurement of intra- and intermolecular KIE.

To show that pivalate is directly involved in the proton abstraction step, stoichiometric experiments with the oxidative addition complexes **3.15b** and **3.16b** derived from **3.12b** and **3.13b** in the absence of either Cs<sub>2</sub>CO<sub>3</sub> or CsOPiv were performed (Scheme 3.5a). Interestingly, no product was observed when only Cs<sub>2</sub>CO<sub>3</sub> (10 equiv) was added to the reaction mixture. Even though amide **1.142b** and sulfonamide **1.143b** were obtained in 28% and 35% respectively in the presence of only CsOPiv (10 equiv), high yields could only be obtained with a mixture of Cs<sub>2</sub>CO<sub>3</sub> (10 equiv) and CsOPiv (3.0 equiv). Therefore, the authors concluded that the Cs<sub>2</sub>CO<sub>3</sub> is involved in the deprotonation of the PivOH ligand on **3.17** after CMD to render the process irreversible by impeding the reopening of the palladacycle and pushing the equilibrium towards **3.18** (Scheme 3.5b). This conclusion was further supported by DFT calculations as acetate derivative of **3.17** was calculated to be a highly energetic ground state structure and could readily revert to the starting material.

**Scheme 3.5:** Stoichiometric experiments to elucidate the role of CsOPiv and Cs<sub>2</sub>CO<sub>3</sub>.

Following this, kinetic studies were performed to obtain the order in substrate, catalyst, ligand and active base. The reaction was found to be of zeroth order in substrate indicating that the oxidative addition is not rate-limiting. The reaction is first order in catalyst. Excess of PCy<sub>3</sub> did not interfere with catalysis as even with a ratio of 12:1 ligand to Pd the reaction rate remained unchanged. Finally, the order in pivalate was found to be 1 for ratios of pivalate/Pd < 3:1. In the case of pivalate/Pd > 3:1 ratio, the zeroth order in pivalate was likely obtained due to saturation kinetics. Additionally, DFT calculations and experimental analysis indicated that pivalate promotes phosphine dissociation by  $\kappa^2$ -coordination, which is essential for the C-H activation to occur.

### 3.2 The effect of $\alpha$ -substitution on the reactivity of Pd(0)-catalyzed C(sp<sup>3</sup>)-H arylation

The field of intramolecular Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation has experienced significant development over the past two decades as it constitutes a straightforward method to introduce molecular complexity from simple precursors. Consequently, many reports of both enantioselective and non-enantioselective Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation methodologies have been disclosed with impressive applications in natural product synthesis and other active compounds.<sup>[36,164]</sup> Throughout these studies, general trends for the activation of different types of C(sp<sup>3</sup>)-H bonds have been observed. For instance, methyl C-H bonds are preferentially activated when in competition with methylene bonds and the presence of a heteroatom in  $\alpha$ -position increasing the acidity of the C-H bond may facilitate the activation process.<sup>[78]</sup> For C(sp<sup>2</sup>)-H activation these effects are well understood as Hammet plots constitute a reliable tool for quantification of the influence of arene substitution.<sup>[50,165–167]</sup> However, for C(sp<sup>3</sup>)-H activation these effects remain unexplored as there is no comparable system for alkyl substituents. Consequently, the design and development of new methods is reliant upon experience and chemical intuition rather than accurate data. This lack of quantitative data in C(sp<sup>3</sup>)-H activation might be attributed to the significant challenge that was until recently the activation of methylene C-H bonds. Recently, we reported a highly reactive Pd/NHC system for the enantioselective activation of methylene bonds (see chapter 2), which enabled the present study.<sup>[168]</sup> In this doctoral thesis we report on the effect of  $\alpha$ -substitution on the reactivity of Pd(0)-catalyzed methylene C(sp<sup>3</sup>)-H activation by measurement and comparison of relative initial rates accompanied by experimental and DFT studies for a complete mechanistic picture.

#### 3.2.1 Optimization of the catalytic system.

At the outset of this study the previously disclosed Pd/NHC catalytic system had to be re-optimized as a substantial induction period was observed during the KIE studies (see chapter 2, Figure 2.1). This induction period, presumably originating from the reduction of the Pd(II) precatalyst to the Pd(0) active species, significantly interfered with the reliable evaluation of the kinetic curves. To overcome this challenge we decided to use Pd/NHC complex **3.19** similar to the ones reported by the Hazari group (Figure 3.1).<sup>[169,170]</sup> The sterically demanding 1-*t*Bu-indenyl ancillary ligand on this catalyst prevents the formation of off-cycle dimeric Pd(I) species by disproportionation, which slows down the generation of the Pd(0) active species. We tested this new catalyst under our optimized conditions with previously synthesized substrate **2.44ah** and stopped parallel experiments at different reaction times. The formation of product **2.45ah** was monitored by <sup>19</sup>F NMR spectroscopy using fluorobenzene as external standard (see experimental section for more details). Pleasingly, when this complex was employed as the catalyst, an induction period was not observed, confirming that catalyst **3.19** is compatible for this study.

**Figure 3.1:** Initial rate experiment of C(sp<sup>3</sup>)-H activation of with substrate **2.44ah** employing new catalyst **3.19**. <sup>a</sup>Determined by <sup>19</sup>F NMR using fluoronobenzene as external standard.

We began this study by examining the effects of different activators which play the role of reducing the Pd(II) precatalyst **3.19** by attacking the 1-*t*Bu-indenyl ligand. The reactions were stopped at *t* = 120 min as a point of reference in order to observe any effect on the rate of the reaction. With the standard conditions product **2.45ah** is formed in 35% yield (Table 3.1, entry 1). Increasing the equivalents of CsOPiv from 0.3 to 0.6 led to a comparable yield of 36% (entry 2). We therefore further increased the loading of CsOPiv to 1.5 equivalents but in this case the yield was decreased probably because the high amount of solids in the reaction mixture interfered with the stirring (entry 3). When KOPiv was used as an additive, a much lower yield was observed. This is consistent with the use of a more sparingly soluble carboxylate salt (entry 4). With the less sterically demanding CsOAc only traces of the product were observed (entry 5). The addition of 1,3-dimethylbarbituric acid (DMBA) was not fruitful and with PivNHOH again only traces of the product were observed (entries 6 and 7).

Entry	activator (equiv)	yield (%) <sup>a</sup>
<b>1</b>	<b>CsOPiv (0.3)</b>	<b>35</b>
2	CsOPiv (0.6)	36
3	CsOPiv (1.5)	30
4	KOPiv (0.3)	19
5	CsOAc (0.3)	9
6	DMBA (0.3)	-
7	PivNHOH (0.3)	2

<sup>a</sup>Determined by <sup>19</sup>F NMR using fluoronobenzene as external standard.

Subsequently we turned our attention to different temperatures and concentrations. When the concentration was increased from 0.1 M to 0.2 M, a marginally higher yield of 38% was observed. However, dilution to 0.05 M almost completely shut down the reaction, as only trace amounts of the product was observed (Table 3.2, entries 1 and 2). Increasing the temperature to 150 °C and 160 °C could have led to catalyst decomposition as only traces of the product was observed (entries 3 and 4).

**Table 3.2:** influence of concentration and temperature on the formation of product **2.145ah**.

Reaction scheme: **2.44ah**  $\xrightarrow[\text{CF}_3\text{Ph, 5Å MS, } T\text{ (}^\circ\text{C), 2 h}]{\text{3.19 (10 mol\%), CsOPiv (0.3 equiv), Cs}_2\text{CO}_3\text{ (1.0 equiv)}}$  **2.45ah**

### 3.2.2 Mechanistic aspects of the Pd(0)-catalyzed methylene C(sp<sup>3</sup>)-H bond activation: KIE, orders in reaction components and stirring rate experiments

Having established a robust catalytic system, we had to ensure that the C-H activation step is rate-limiting before examining the reactivity of different C-H bonds. This would enable us to conclude that differences in the rate could be attributed to differences in the C-H bonds, rather than a different process in the reaction. Thus, we performed intermolecular parallel KIE experiments with substrates **2.44ah** and **2.44ah-d<sub>5</sub>** and obtained a value of 3.5, which confirms that the proton abstraction process is rate-limiting (Figure 3.2). Additionally, the calculated value of 4.8 is in accordance with our experimental observation. Based on these results, it is likely that the C-H activation is the rate-limiting step and that differences in the observed initial rates will be correlated to the differences in the reactivity of C-H bonds with differing α-substituents.

**Figure 3.2:** Parallel KIE experiments with substrates **2.44ah** and **2.44ah-d<sub>5</sub>**. <sup>a</sup>Determined by <sup>19</sup>F NMR using fluoronobenzene as external standard.

To obtain deeper insights into the reaction mechanism the order of each reaction component was determined using the Variable Time Normalization Analysis (VTNA) developed by Burés in collaboration with Dr. Matthew Wheatley.<sup>[171]</sup> This method enables kinetic data to be gathered using relatively few data points and is determined by the overlay of the graphs.

Initially we examined the order in substrate, as this was reported to be zero order by Fagnou. Initial rate experiments at 0.1 M (black squares) and 0.2 M (red triangles) of **2.44ah** led to overlay of the curves when the exponent was set to 0 (Figure 3.3a). Zeroth order in substrate suggests that oxidative addition is not rate-limiting which is in accordance to the positive KIE. As expected, the reaction is first order in catalyst as observed with experiments at 0.01 M (black triangles) and 0.02 M (red squares) catalyst concentration. This supports the KIE suggesting that C–H activation is the rate-limiting step as it means that this step is on-cycle. In the study of the Baudoin group, Cs<sub>2</sub>CO<sub>3</sub> acted as the active base. In this case, zeroth order was observed in Cs<sub>2</sub>CO<sub>3</sub>, however this can be explained by poor solubility of this component in CF<sub>3</sub>Ph. Finally, the order in pivalate was found to be 0 for concentrations of 0.015 M (blue triangles) 0.03 M (orange squares) and 0.06 M (black circles) (Figure 3.3d). This is in contrast to the report of Fagnou employing a Pd(0)/phosphine catalytic system where an order of 1 was observed for ratios of pivalate/Pd < 3:1 whereas saturation kinetics were observed for a ratio of pivalate/Pd > 3:1. Zeroth order in pivalate for our case could be explained by the pivalate being involved in the off-cycle activation of the Pd(II) precatalyst but not in the C–H activation step. However, upon examining the solubility of CsOPiv in CF<sub>3</sub>Ph, it was found to be insoluble at even low concentrations. This means that it is possible that the zero order kinetics we observe are as a direct result of saturation with respect to the concentration of CsOPiv, whereby adding more of this component does not increase the amount of this species in solution.

**Figure 3.3:** Determination of order in a. substrate, b. catalyst, c.  $\text{Cs}_2\text{CO}_3$  and d. CsOPiv by VTNA.

Next, we examined the influence of the stirring on the rate of the reaction. Since the reaction set up is heterogeneous, the stirring rate might affect the concentration of a component which is involved in the rate-limiting step such as CsOPiv or Cs<sub>2</sub>CO<sub>3</sub>.<sup>[172,173]</sup> Indeed, when the reaction was stirred at a rate of 250 rpm (blue crosses) almost no product was observed (Figure 3.4). When comparing these results with the standard stirring rate for these reactions (1000 rpm, purple squares) it is clear that there is a significant difference in the reaction due to the stirring rate. This is a result of the Gibbs-Thomson effect, as smaller particles have a higher chemical potential and therefore more of the compound is solvated. The increase in reaction rate with higher concentration of the species in solution, suggests that one or both scarcely soluble reaction components (Cs<sub>2</sub>CO<sub>3</sub> or CsOPiv) play an important role in the C–H abstraction process.

**Figure 3.4:** influence of stirring on reaction rate. <sup>a</sup>Determined by <sup>19</sup>F NMR using fluoronobenzene as external standard.

Based on the obtained data supported by DFT calculations (see section 3.2.4) and on the results of previous mechanistic studies, we propose the following catalytic cycle for the Pd(0)-catalyzed methylene C(sp<sup>3</sup>)–H bond activation shown in Scheme 3.6. First, precatalyst **3.19** is reduced to the Pd(0) active species. Reports by the Nolan group for similar Pd/NHC systems suggest that this process occurs by nucleophilic attack of an activator species on the alkenyl ancillary ligand.<sup>[174,175]</sup> Unfortunately, stoichiometric experiments with only precatalyst **3.19** and CsOPiv as activator have as yet failed to give structure **3.20**. However, this is perhaps due to a challenging ligand exchange being required. After generating the active Pd(0) species, it oxidatively inserts into the C–Br bond to give complex **3.21**. Subsequent ligand exchange with a carboxylate ligand gives intermediate **3.22** from which C–H bond activation via a CMD transition state (**3.23**) takes place leading to palladacycle **3.24**. Finally, reductive elimination closes the new 5-membered ring giving indanes **2.45** and restores the Pd(0) active species.

**Scheme 3.6:** Proposed catalytic cycle for the Pd(0)-catalyzed activation of methylene C–H bonds.

### 3.2.3 Influence of $\alpha$ -substitution on the reactivity of methylene C(sp<sup>3</sup>)–H bonds

Having studied the general aspects of the mechanism and showed that the C–H activation step is likely to be rate-limiting, we turned our attention to the influence of  $\alpha$ -substitution on the reaction rate. We envisioned using substrate **2.44ah** as the base line and set the obtained relative rate to 1 (Figure 3.5). Consequently, the rates obtained with the other substrates are set on scale compared to the base line rate of 1. The substrate featuring the most acidic C–H bond (**2.44ak**, R = CO<sub>2</sub>Me) displayed the fastest rate with a reaction 22.1 times faster than the standard reaction. On the other side of the scale, substrate **2.44ap** bearing a OMe group in  $\alpha$ -position reacted much more slowly with a relative rate of 0.583. In between these two substrates, the observed trends were not trivial. For instance, the activation of a cyclopropyl C–H bond on substrate **2.44al** occurs 15.8 times faster than the standard reaction. In this particular case, spirocyclic product **2.45al** was obtained by activation of the most hindered position, underlining the preference for the formation of a 6-membered palladacycle. The observed high rate is presumably attributed to the increased sp<sup>2</sup> character of the C–H bond associated with strained cyclopropane rings.<sup>[176]</sup> Substrate **2.44am**, where R = CONMe<sub>2</sub> reacted 15.2 times faster. When compared to substrate **2.44ak** the slower reaction rate is in line with the lesser electron-withdrawing ability of amides relative to esters, which is translated in lower acidity of the C–H bond. For the activation of the methyl C–H bond on substrate **2.44an** a higher reaction rate was observed compared to the activation of the benzylic C–H bond (**2.44ao**) although the pK<sub>a</sub> value of a methyl proton is significantly higher than that of a benzylic proton (~56 vs.~43). This suggests that the rate of activation is not solely dependent on the electronic nature of the C–H bond but steric effects have a significant impact. In summary, this leads to the following overall order of activation: CO<sub>2</sub>Me (**2.44ak**) > *c*Pr (**2.44al**) > CONMe<sub>2</sub> (**2.44am**) > H (**2.44an**) >> Ph (**2.44ao**) > Me (**2.44ah**) > OMe (**2.44ap**).

**Figure 3.5:** Initial rate experiments to determine the relative rate constants  $k_{rel}$ . <sup>a</sup>Determined by <sup>19</sup>F NMR using fluoronobenzene as external standard.

### 3.2.4 DFT calculations

To support our experimental data, DFT calculations were performed using the BP86 functional in collaboration with Prof. Dr. Stuart A. Macgregor. As experimental evidence for the role of CsOPiv and Cs<sub>2</sub>CO<sub>3</sub> has thus far proven to be elusive, both reaction profiles were calculated individually using our model substrate **2.44ah** (R = Me group) at 413 K. Setting oxidative addition complex **3.25** as the zero point, an energy barrier of 26.7 kcal mol<sup>-1</sup> was calculated for the C–H activation step via transition state **TS(3.25-3.26)** (Scheme 3.7a). From palladacycle **3.26**, reductive elimination with the protonated carbonate base still coordinated to the Pd center goes through the highly energetic transition state **TS(3.26-3.28)** with an energy barrier of 24.3 kcal mol<sup>-1</sup>. However, from intermediate **3.27**, formed after dissociation of HCO<sub>3</sub><sup>-</sup>, reductive elimination is energetically more favorable leading to the product **2.45ah** over transition state **TS(3.27-2.45ah)** which lies 12.5 kcal mol<sup>-1</sup> lower in energy. Overall, the C–H activation process is computed to be rate-limiting which is in accordance to our experimentally obtained positive KIE value. With CsOPiv as the active base, the proton abstraction process takes place from intermediate **I(3.28-3.29)** (Scheme 3.7b). Again, reductive elimination with coordinated PivOH (**3.29**) is less favorable than from palladacycle **3.30** ( $\Delta G^\ddagger$  15.0 vs 11.5 kcal mol<sup>-1</sup>). However, in this reaction profile the reductive elimination step lies higher in energy than the C–H activation.

### 3.3 Conclusion

We have studied the influence of  $\alpha$ -substitution on the activation rate of methylene C–H bond. Key for the realization of this study was our previously disclosed Pd/NHC catalytic system capable of activating unreactive secondary C–H bonds in ring forming reactions. A significant KIE for the proton abstraction process and kinetic analysis by VTNA showed an order 1 in catalyst and 0 in substrate, which are in line with the C–H activation being rate-limiting. In contrast to previous reports, order 0 in pivalate was observed suggesting that this species is not involved in the rate-limiting step. However, due to the poor solubility of this component in  $\text{CF}_3\text{Ph}$ , the observed zero order might be a consequence of saturation kinetics. DFT calculations indicate that the carbonate base is promoting the C–H bond abstraction rather than the pivalate. Having disclosed the fundamental information suggesting that the comparison of different C–H bonds would be relevant to the overall rate of the reaction, we performed initial rate experiments to construct a reactivity scale quantifying the effect of  $\alpha$ -substituents on the C–H activation rate. This allowed us to categorically order the substituents in a series of most to least reactive. From the obtained data, it can be concluded that the rate of activation is not only affected by the electronic properties (pKa) of the C–H bond but also by its steric environment. Overall, the presented scale represents a fundamental tool for the design of future  $\text{C}(\text{sp}^3)\text{--H}$  activation studies where the reaction outcome can be directed by judicious choice of the  $\alpha$ -substituent influencing the electronic and steric properties of the targeted C–H bond.

## Chapter 4: Enantioselective remote C(sp<sup>3</sup>)-H activation by 1,4-Pd shift

### 4.1 Introduction

Intramolecular 1,4-Pd shift has strongly gained importance over the past decades as it constitutes an elegant and straightforward strategy to functionalize C-H bonds in remote positions to the initial C-Pd site. This has enabled the synthesis of important value added small molecules which would be otherwise difficult to access.<sup>[177-179]</sup> The ability of Pd to undergo a 1,4-shift was initially reported by Heck in 1972. The reaction of  $\sigma$ -Pd complex **4.1** formed in situ from (2-methyl-2-phenyl)mercury acetate and Pd(OAc)<sub>2</sub>, led to a 65:35 mixture of products **4.2** and **4.3** (Scheme 4.1). Product **4.2** was formed through direct migratory insertion of methyl acrylate into the Pd-C bond followed by  $\beta$ -H elimination. Compound **4.3** however, was formed through intermediate **4.5** arising from *ortho*-C(sp<sup>2</sup>)-H activation and reopening of the palladacycle (proposed mechanism). Following this observation, the first example of C(sp<sup>3</sup>)-H activation shifting Pd on an alkyl substituent was reported by Dyker in 1992 (see chapter 1, section 1.2.2).<sup>[71]</sup>

**Scheme 4.1:** First report of 1,4-Pd shift.

Based on this pioneering work numerous reports followed on the formation of new remote C(sp<sup>2</sup>)-C(sp<sup>2</sup>), C(sp<sup>3</sup>)-C(sp<sup>2</sup>) and C-X (X= heteroatom) bonds exploiting cross-coupling reactions such as Mizoroki-Heck, Suzuki-Miyaura, Buchwald-Hartwig, trapping of the nucleophilic aryl- or alkyl-palladium intermediate with alkynes or by termination of the reaction by  $\beta$ -H elimination.<sup>[178,180,181]</sup> The first example of Pd(0)-catalyzed tandem 1,4-shift/C(sp<sup>2</sup>)-H activation was reported by Larock in 2003 (Scheme 4.2).<sup>[182]</sup> Fused polycycles of type **4.9** were prepared from biaryl iodide precursors **4.7**. In this case Pd migrates to the second aromatic ring by C(sp<sup>2</sup>)-H activation and subsequent opening of the palladacycle leading to intermediate **4.8** from which a second C(sp<sup>2</sup>)-H activation and reductive elimination forms the 5-membered ring.

**Scheme 4.2:** First example of ring forming 1,4-Pd shift/C(sp<sup>2</sup>)-H activation reaction.

As part of the long-standing research interest in the Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation, the Baudoin group focused on the formation of small rings remote to the original oxidative addition site exploiting Pd-mediated 1,4-shifts. In 2019, the synthesis of  $\alpha$ -arylidene  $\gamma$ -lactams **4.11** and indanones **4.12** was disclosed in good to high yields (Scheme 4.3a).<sup>[183]</sup> Similar to the report of Larock, the Pd shifted to a sp<sup>2</sup> hybridized carbon via C-H bond activation and subsequent opening of the palladacycle, however in this case the ring was closed by the abstraction of the less reactive C(sp<sup>3</sup>)-H bond. The usefulness of the method was demonstrated in the total synthesis of the pyrrolizidine alkaloid (–)-pyrrolam A (**4.15**) (Scheme 4.3b). Precursor **4.10a** for the Pd(0)-catalyzed 1,4-Pd shift/C(sp<sup>3</sup>)-H activation reaction was prepared by amide coupling from 2-bromocinnamic acid (**4.13**) and (*S*)-2-methyl-pyrrolidine (**4.14**) in quantitative yield. Subjecting **4.10a** to the optimized conditions gave  $\alpha$ -arylidene  $\gamma$ -lactam product **4.11a** in moderate 50% yield. From this intermediate, the natural product was previously prepared in three additional steps.<sup>[184]</sup> Thus, the reported approach allows for the synthesis of pyrrolam A (**4.15**) in five steps, which is two steps shorter than the first total synthesis.<sup>[184]</sup>

**Scheme 4.3:** a. Synthesis of  $\alpha$ -arylidene  $\gamma$ -lactams **4.11** and indanones **4.12** by 1,4-Pd shift/C(sp<sup>3</sup>)-H activation. b. Application in the total synthesis of (–)-pyrrolam A (**4.15**)

Later, the same group reported the 1,4-shift of Pd onto a C(sp<sup>3</sup>) site prior to C(sp<sup>3</sup>)-H bond activation.<sup>[185]</sup> With this strategy dihydrobenzofurans **4.18** and indolines **4.19** could be accessed from the corresponding aryl bromide precursors **4.16** and **4.17** respectively in good to high yields (Scheme 4.4). In this case, the preparation of structures **4.18** and **4.19** can be realized without the need of a quaternary carbon otherwise required for ring contraction in direct intramolecular C(sp<sup>3</sup>)-H activation (Scheme 4.4a). Moreover, the method could be applied to form 6-membered rings by activating a highly acidic secondary C(sp<sup>3</sup>)-H bond. Chromanones of type **4.21** were accessed from aryl bromides **4.20** with modified reaction conditions (Scheme 4.4b). Additionally, a different type of C(sp<sup>3</sup>)-C(sp<sup>3</sup>) bond formation was explored using benzophenone substrates **4.22** lacking an enolizable position.

Products **4.23** featuring tertiary alcohols were prepared by a tandem 1,4-Pd shift/nucleophilic attack of the carbonyl moiety. However, these products were prone to elimination as benzofurans **4.24** were observed when left in  $\text{CDCl}_3$  at room temperature for an extended period of time (Scheme 4.4c).

**Scheme 4.4:** First report of 1,4-Pd shift on a  $\text{C}(\text{sp}^3)$  site to form new  $\text{C}(\text{sp}^3)\text{--C}(\text{sp}^3)$  bonds. a. Synthesis of dihydrobenzofurans **4.18** and indolines **4.19**. b. Preparation of chromanones **4.21** by 6-membered ring formation. c. Formation of quaternary alcohols by tandem 1,4-Pd shift and nucleophilic attack of the carbonyl.

One year later the same group disclosed the first protocol for the formation of highly strained cyclopropanes by sequential Pd(0)-catalyzed  $\text{C}(\text{sp}^3)\text{--H}$  activation reactions.<sup>[186]</sup> When aryl bromides or triflates **4.25** were subjected to catalytic amounts of  $\text{Pd}(\text{PPh}_3)_4$ , benzylic cyclopropanes **4.26** were formed over 1,4-palladium shift (Scheme 4.5). In this case, the shift could occur on both, methyl or methylene positions. Interestingly, the nature of the active base played a fundamental role in this particular reaction. For instance, in presence of  $\text{K}_2\text{CO}_3$  direct C–H activation product **4.27a** was observed from arylbromide **4.25a** in 46%. However, using KOiPr favors formation of **4.26a** without any traces of benzocyclobutene **4.27a**.

**Scheme 4.5:** Synthesis of cyclopropanes by 1,4-Pd shift.

The method was applied in the synthesis of bioactive molecules containing cyclopropyl moieties and the total synthesis of lemborexant (**4.34**) that is used for the treatment of insomnia (Scheme 4.6).<sup>[187]</sup> Substrate **4.29** was prepared from commercially available **4.28** in 5 steps. The key cyclopropanation over 1,4-Pd shift gave product **4.30**, that was subsequently elaborated to structure **4.32** by amidation with aminopyridine **4.31** as described by the Szostak group.<sup>[188]</sup> Finally, Mitsunobu reaction with parimidinol **4.33** led to ( $\pm$ )-lemborexant (**4.34**) in 28% overall yield over 8 steps.

**Scheme 4.6:** Total synthesis of (±)-lemborexant (4.34) by 1,4-Pd shift.

Very recently, the Baudoin group designed and optimized a Pd(0)/NHC catalytic system for the formation of isoindolines **4.36** and  $\gamma$ -lactams **4.38** by 1,4-Pd shift (Scheme 4.7).<sup>[189]</sup> After oxidative addition on aryl bromide substrates **4.35** and **4.37**, the Pd atom migrates to the methyl substituent on the nitrogen forming a  $\sigma$ -alkylpalladium intermediate, that subsequently undergoes C(sp<sup>2</sup>)-H or C(sp<sup>3</sup>)-H bond activation, respectively. In both cases the NHC ligand was key to obtain the remote C-H activation product as with phosphine based ligands mainly direct C-H activation was observed.

**Scheme 4.7:** Synthesis of isoindolines **4.36** and  $\gamma$ -lactams **4.38** by 1,4-Pd shift and trapping with C(sp<sup>2</sup>)-H or C(sp<sup>3</sup>)-H activation respectively.

## 4.2 Studies on Pd(0)-catalyzed enantioselective remote C(sp<sup>3</sup>)-H activation

The activation of remote C(sp<sup>3</sup>)-H bonds by 1,4-Pd shift allows for the preparation of structurally distinct molecules relevant to the pharmaceutical and agrochemical industry that would otherwise not be accessible by direct C-H activation methods.<sup>[183,185,186,189]</sup> This enables the direct access of target compounds avoiding additional steps to remove undesired structural motifs. The design and development of new enantioselective methods is a long-standing challenge in synthetic organic chemistry as the activity in biological systems of such compounds is directly linked to their three dimensional arrangement.<sup>[104,105]</sup> We therefore envisioned that the design of enantioselective activation of remote C(sp<sup>3</sup>)-H bonds would strongly contribute to the progress of the development of new and more effective drugs and other active compounds. Herein, we report on our studies on the construction of a Pd(0)-catalyzed system for the activation of remote C(sp<sup>3</sup>)-H bonds by 1,4-Pd shift.

### 4.2.1 Enantioselective synthesis of oxygen containing heterocycles.

We began our investigations on enantioselective tandem 1,4-Pd shift/C(sp<sup>3</sup>)-H activation by reevaluating the previously disclosed reaction to form benzofurans **4.18** from arylbromides **4.16**.<sup>[185]</sup> We were pleased to see that product **4.18a** was formed in 49% employing our previously disclosed Pd/NHC conditions for the activation of methylene C(sp<sup>3</sup>)-H bonds in presence of racemic ligand IBiox6 (Table 4.1, entry 1).

**Table 4.1:** Screening of ligands for enantioselective 1,4-Pd shift.

Entry	conditions <sup>a</sup>	L	Product ratio <sup>a</sup>				e.r. <sup>b</sup>
			4.18a	4.39a	4.16a	others

5	b	<b>L4.1</b>	-	13	87	-	n.d. <sup>c</sup>

<sup>a</sup>Determined by GC-MS. <sup>b</sup>Determined by HPLC on a chiral stationary phase. <sup>c</sup>n.d. = not determined.

With chiral ligand IBioxAd however, only 22% of the product were formed with 11% of proto-dehalogenated byproduct **4.39a** and 75% of starting material **4.16a**. Analysis by HPLC on a chiral stationary phase gave an e.r. of 48:52 (entry 2). With IBiox*t*Bu only traces of the product were observed and therefore the enantioinduction

could not be analyzed (entry 3). Chiral phosphonite **L2.5d** and binol-derived phosphoramidite **L4.1** were not productive leading to the observation of mainly starting material **4.16a** in both cases (entries 4 and 5).

Focusing on the most efficient conditions, we evaluated a different Pd source, solvent and removed the additive to improve the previously obtained e.r. When [Pd(<sup>1</sup>-tBuInd)Cl]<sub>2</sub> as the Pd(0) was used, a decrease in reactivity was observed, giving a product formation of only 11% (Table 4.2, entry 1). Changing the solvent to CH<sub>3</sub>Ph or removing the 5 Å molecular sieves from the reaction mixture was not fruitful as in both cases no product formation was observed (entries 2 and 3)

**Table 4.2:** Influence of different Pd-source, solvent and removal of additives.

Entry	Deviation from standard conditions	Product ratio <sup>a</sup>					e.r. <sup>b</sup>

<sup>a</sup>Determined by GC-MS. <sup>b</sup>Determined by HPLC on a chiral stationary phase. <sup>c</sup>n.d. = not determined.

Presumably, the poor e.r. might be derived from the higher acidity of the doubly activated C(sp<sup>3</sup>)-H bond in substrate **4.16a**. We tested substrates **4.16b-d** with different α-substituents to tune the electronic properties of the targeted C(sp<sup>3</sup>)-H bond. We therefore subjected substrate **4.16b** featuring a pivalate group in α-position to the target methylene C(sp<sup>3</sup>)-H bond to the previously reported conditions for 1,4-Pd shift.<sup>[185]</sup> Unfortunately, only proto-dehalogenation byproduct **4.39b** along with unreacted starting material was observed (Table 4.3, entry 1). Changing the α-substituent to a less sterically congested acetate group (**4.16c**) did not give the corresponding product (entry 2). Finally, with substrate **4.16c** bearing a NPhth group adjacent to the C-H bond, no reaction occurred after 18 h reaction time and only starting material was recovered (entry 3).

**Table 4.3:** Screening of substrates with different α-substituent on the second C-H bond.

We turned our attention to the alkylation of cyclopropanes. Due to their unique electronic properties, <sup>[133,135,190]</sup>cyclopropane C–H bonds have been easily functionalized by means of Pd(0)-catalyzed C–H activation in the past (see chapters 1 and 2). Under the optimized 1,4-Pd shift conditions with substrate **4.16e** no product was observed (Table 4.4, entry 1). Subjecting starting material **4.16e** to our racemic Pd/NHC conditions in presence of IBiox6 was not fruitful (entry 2). With Pd(dba)<sub>2</sub> and PCy<sub>3</sub> forming the catalytic active Pd(0)(PCy<sub>3</sub>)<sub>2</sub> species in situ in presence of PivOH in CH<sub>3</sub>Ph no reaction occurred (entry 3). The same outcome was observed in *p*-xylene instead of CH<sub>3</sub>Ph (entries 4).

**Table 4.4** screening of condition sets previously employed in direct C–H activation.

#### 4.2.2 Synthesis of chromanones

Since with substrates **4.16b-d** no product was observed, we concluded that the pK<sub>a</sub> of the target C–H bonds was too high. This hypothesis is further supported by occurring proto-dehalogenation meaning that oxidative addition takes place but then dehalogenation is favored over C–H activation. Therefore, in parallel to the studies with substrate **4.16e**, we examined the previously disclosed reaction to form chromanones **4.21** from arylbromides **4.20**.<sup>[185]</sup> Subjecting substrate **4.20a** to the reported conditions with Pd(PCy<sub>3</sub>)<sub>2</sub> as catalyst to obtain a racemic reference led to a product formation of 31% along with 12% proto-dehalogenation product **4.40a** (Table 4.5, entry 1). Using the well-defined Pd(PCy<sub>3</sub>)<sub>2</sub> complex led to a similar product formation of 32% (entry 2). Nevertheless, enough material in acceptable purity was obtained for HPLC analysis on a chiral stationary phase. Subsequently, we turned our attention to the screening of chiral ligands. In presence of phosphoramidite ligands **L4.1** and **L1.2b** no product or only traces were obtained (entries 3 and 4). A similar outcome was observed with binepine **L2.4b** and phosphonite **L4.2** (entries 5 and 6).

**Table 4.5:** Screening of chiral ligands for the synthesis of chromanone **4.21a**.

Pleasingly, in presence of monodentate chiral phosphine **L4.3** 45% of product **4.21a** was formed. However, analysis of the enantioselectivity gave an e.r. of 49:51 (entry 7).

### 4.3 Conclusion

The Pd(0)-catalyzed activation of remote C(sp<sup>3</sup>)-H bonds exploiting the ability of the catalyst to migrate in a 1,4 fashion has experienced great momentum in the past five years. To date, highly desirable enantioselective protocols remain unexplored. To this end, we conducted preliminary studies on enantioselective activation of remote C(sp<sup>3</sup>)-H activation by designing and preparing new substrates and reevaluating racemic reactions previously reported by our group for the formation of oxygen containing heterocycles and chromanones. Preliminary evaluation of chiral ligand classes previously employed in asymmetric Pd(0)-catalyzed C-H activation were not fruitful leading in most cases to recovery of the starting material or only traces of the product. Tweaking the acidity of the C-H bond to trap the  $\sigma$ -alkylpalladium intermediate by changing the  $\alpha$ -substituent did not lead to any improvement. However, with a strongly electron donating chiral NHC and a monodentate phosphine ligand substantial product formation was observed albeit in poor enantioselectivity. In conclusion our preliminary results show that chiral ligands are able to promote the ring closure by activation of the second C-H bond but the two important points have to be addressed for high levels of enantioselectivities. (1) The second C-H bond must not be too acidic to prevent racemization after forming the product and (2) a reactive chiral ligand with suitable steric properties to favor one enantiomer over the other has to be found.

## 5. General conclusions

This doctoral thesis presents the development of a new, highly reactive Pd(0)/NHC\* catalytic system for the activation of enantiotopic secondary C–H bonds to form chiral indanes. The stereogenic center was thereby created at the C–H activation site in contrast to the desymmetrization of prochiral alkyl groups, which dominates the field. After a thorough screening of ligand families previously applied in enantioselective C–H activation methods, the IBioxR NHC ligands showed a unique reactivity towards the activation of methylene C–H bonds, outperforming other carbene and phosphorus containing ligands. Employing the IBioxAd derivative, a variety of substituted chiral indanes could be accessed in high yields and enantioselectivities including 3<sup>ary</sup> amides substituted products featuring a labile stereogenic center. An analysis of the sterical properties of the IBiox-type ligands revealed that the %  $V_{\text{Bur}}$  is not directly correlated with the observed enantioinduction. However, it was found that the e.r. value increases as a function of the %  $V_{\text{Bur(QD)}}$ . Moreover, the developed enantioselective methodology was proven compatible for the formation of the chiral indane core structure of prenylated flavonoid natural products indidene A-C and renifolin D-H in consistent high enantioselectivity.

Synthesis of chiral indanes by activation of secondary C–H bonds

The developed methodology for the activation of methylene C–H bonds set the stage for mechanistic studies on the influence of  $\alpha$ -substitution on the reactivity of C(sp<sup>3</sup>)–H bonds. Initial kinetic analysis of the reaction and a significant primary KIE confirmed the C–H abstraction step to be rate-limiting ensuring that the comparison of different C–H bonds was significant. Thus, initial rate experiments with substrates featuring C–H bonds differing in electronic and steric properties were performed to construct a scale, ranking them from most to least reactive. It was found that the C(sp<sup>3</sup>)–H bond in  $\alpha$ -position to an ester reacts the fastest and, on the other side of the spectrum, OMe substituted C–H bond was the slowest with an overall 37.8-fold difference in initial rate. The order within the series however, proved to not be trivial leading to the following complete series  $\alpha$ -substituted C–H bonds with R = CO<sub>2</sub>Me > cC<sub>2</sub>H<sub>4</sub> > CONMe<sub>2</sub> > H >> Ph > Me > OMe. Additionally, the calculation of the energy barrier for the different C–H bonds by DFT methods on a simplified model partially support the experimental trend. In general, the rate of C(sp<sup>3</sup>)–H bond is not solely dependent on electronic properties (acidity) but the steric environment has a significant impact. The disclosed reactivity scale quantifying the effect of  $\alpha$ -substitution on the reactivity of C(sp<sup>3</sup>)–H bonds can be used as a guide for the development of new Pd(0)-catalyzed methylene C–H bond activation methods.

Construction of a reactivity scale for Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation

Finally, initial progress was made on the development of an enantioselective methodology for the activation of remote C(sp<sup>3</sup>)-H bonds enabled by 1,4-Pd shift. A preliminary screening of chiral ligands led to the observation of the product featuring a new 5-or 6-membered ring in poor selectivity. This suggests that the geometry of the ligand backbone is not ideal for high enantioinduction.

## 6. Experimental part

### General methods

#### Techniques:

All reactions involving air-sensitive compounds were carried out in pre-dried glassware under an argon atmosphere by using Schlenk techniques employing double-line argon-vacuum lines and working in an argon-filled glove box. Analytical thin layer chromatography (TLC) was performed using pre-coated Merck silica gel 60 F254 plates (0.25 mm). Visualization of the developed chromatogram was performed by UV absorbance (254 nm) or TLC stains ( $\text{KMnO}_4$  and Phosphomolybdic acid). Flash chromatography was performed using Silicycle SiliaFlash P60 (230-400 mesh) with the indicated solvent system, using gradients of increasing polarity in most cases.

#### Chemicals:

Anhydrous solvents were purchased from Acros Organics or Sigma-Aldrich. The solvents were degassed by three cycles of freeze-pump-thaw and storing in single-necked flasks equipped with a J-Young PTFE valve when necessary. Palladium complexes were purchased from Sigma-Aldrich or Strem. All other chemical reagents were purchased from Sigma-Aldrich, Acros Organics, Alfa Aesar Apollo scientific and Fluorochem and used as received without further purification unless otherwise stated.

#### Instrumentation:

GCMS analyses were performed with a Shimadzu QP2010SB GCMS apparatus on a Rtx®-5ms-Low-Bleed column lined with a mass (EI) detection system. HPLC analyses were performed using a Shimadzu Prominence system with SIL-20A auto sampler, CTO-20AC column oven, LC-20AD pump system, DGU-20A3 degasser and SPD-M20A Diode Array or UV/VIS detector. The following chiral columns from Daicel Chemical Industries were used: OD-H (Chiralcel®), OJ-H (Chiralcel®), IA (Chiralpak®) in 4.6 x 250 mm size. Melting points were obtained on a Büchi melting point M-565, and are uncorrected. IR spectra were recorded on an ATR Varian Scimitar 800 and are reported in reciprocal centimeters ( $\text{cm}^{-1}$ ). Nuclear magnetic resonance spectra were recorded on a Bruker Advance 400 (400 MHz), Advance 500 (500 MHz) and Advance 600 (600 MHz) in deuterated chloroform (residual peaks  $^1\text{H}$   $\delta$  7.26 ppm,  $^{13}\text{C}$   $\delta$  77.16 ppm) unless otherwise noted.  $^{19}\text{F}$  NMR spectra were referenced to external  $\text{CFCl}_3$ . Both,  $^{13}\text{C}$  and  $^{19}\text{F}$  NMR spectra are  $^1\text{H}$  ( $\{^1\text{H}\}$ ) decoupled unless otherwise stated. Data are reported in parts per million (ppm) as follows: chemical shift, multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, quint = quintuplet, sept = septuplet, m = multiplet and brs = broad singlet), coupling constant in Hz and integration. High resolution mass spectra were recorded by Dr. M. Pfeffer and S. Mittelheisser (Department of Chemistry, University of Basel) on a Bruker maXis 4G QTOF ESI mass spectrometer. Optical rotations were measured on a Anton Paar MCP 100 Polarimeter in a 0.7 mL micro cuvette (cell length 100mm) with NaD-Line ( $\lambda = 589 \text{ nm}$ ). The concentration (c) was given in g/100 mL.

## 6.1 Palladium(0)-catalyzed enantioselective intramolecular arylation of enantiotopic secondary C–H bonds for the synthesis of chiral indanes

### 6.1.1 Synthesis of IBioxR ligands and well-defined Pd-complexes

All IBiox-type ligands were prepared as reported<sup>[147,191,192]</sup> from different amino acids according to the following sequence:

#### General procedure A: reduction of the amino acids

The amino acid (1 equiv), and NaBH<sub>4</sub> (3 equiv), and THF (4 mL/mmol of amino acid) were added to a dry round-bottom flask and cooled to 0 °C. A solution I<sub>2</sub> (1 equiv) in THF (2 mL/mmol of I<sub>2</sub>) was added dropwise, allowing the mixture to turn white after each drop. Following the addition, the mixture was heated to reflux for 15 hours. The reaction mixture was then cooled to 0 °C and quenched slowly with MeOH. The solvents were removed in vacuo, and the remaining solid was dissolved in 20% aqueous solution of KOH and stirred at 50 °C for 1.5 hours. The mixture was cooled to room temperature, extracted with EtOAc, and the combined organic extracts were dried over MgSO<sub>4</sub> and filtered. The solvent was removed in vacuo, and the crude aminoalcohol taken forward.

#### General procedure B: bisoxazoline synthesis

Aminoalcohol (2.1 equiv) and diethyloxalate (1.0 equiv) were stirred at reflux in toluene (2.5 mL/mmol of aminoalcohol) overnight. The reaction was then concentrated. The obtained solid was washed with petroleum ether and dried to afford the desired oxalamide which was used without further purification. SOCl<sub>2</sub> (2.9 equiv) was added to a suspension of the previously obtained oxalamide (1 equiv) in toluene (10 mL/mmol of oxalamide) at 60 °C. The solution was stirred at this temperature for 1 h and then 3 h at 90 °C. After this time, the reaction was quenched with methanol and concentrated. The residue was taken up in CH<sub>2</sub>Cl<sub>2</sub> and vigorously washed with a 20% (w/v) aqueous solution of KOH. Layers were separated and the aqueous layer was extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic phases were washed with brine, dried over MgSO<sub>4</sub> and concentrated to yield the desired chlorooxalamide taken forward. To a solution of the previously obtained chlorooxalamide (1 equiv) in THF (20 mL/mmol of chlorooxalamide) a solution of NaOH (2.1 equiv) in ethanol (3 mL/mmol of NaOH) was added. After stirring at ambient temperature for 30 min the mixture was heated at 90 °C for 3 h. The solvent was evaporated, and the residue taken up in MTBE, washed with a saturated aqueous solution of Na<sub>2</sub>CO<sub>3</sub> and dried over MgSO<sub>4</sub>. After concentration, the crude mixture was purified by flash column chromatography (cyclohexane/EtOAc) to yield the desired bisoxazoline.

### General procedure C: cyclization for NHC formation

To a suspension of AgOTf (1.45 equiv) in CH<sub>2</sub>Cl<sub>2</sub> (4.5 mL/mmol of bisoxazoline) was added chloromethyl pivalate (1.45 equiv) and the resulting suspension was stirred for 45 min in the dark. The supernatant was transferred via syringe to the bioxazoline (1 equiv) and the resulting solution was stirred in a sealed tube in the dark at 40 °C for 24 h. After the solution was cooled to room temperature, the solvent was evaporated in vacuo. The resulting oil was chromatographed on silica gel (CH<sub>2</sub>Cl<sub>2</sub>/MeOH) to afford the corresponding IBiox·HOTf.

#### (3*S*,7*S*)-3,7-diisobutyl-2,3,7,8-tetrahydroimidazo[4,3-*b*:5,1-*b'*]bis(oxazole)-4-ium triflate (IBiox<sup>i</sup>Bu·HOTf):

From Biox<sup>i</sup>Bu using General procedure C. IBiox<sup>i</sup>Bu·HOTf was obtained as a wax (178 mg, 0.43 mmol, 15%).

<sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>): δ (ppm) 8.57 (s, 1H), 5.15 (dd, *J* = 8.8, 7.4 Hz, 2H), 4.98-4.92 (m, 2H), 4.66 (dd, *J* = 8.8, 6.2 Hz, 2H), 2.10-2.02 (m, 2H), 1.76-1.66 (m, 4H), 1.00 (d, *J* = 6.4 Hz, 6H), 1.00 (d, *J* = 6.4 Hz, 6H)

<sup>13</sup>C NMR (126 MHz, CDCl<sub>3</sub>): δ (ppm) 125.7, 120.8 (q, *J* = 320.2 Hz), 115.3, 82.2, 58.0, 41.7, 25.3, 22.5, 22.2

<sup>19</sup>F NMR (471 MHz, CDCl<sub>3</sub>): δ (ppm) -78.4.

IR (neat): ν (cm<sup>-1</sup>) 2962, 1731, 1525, 1469, 1253, 1153, 1028, 635.

HRMS (ESI): Calcd for C<sub>15</sub>H<sub>25</sub>N<sub>2</sub>O<sub>2</sub><sup>+</sup> [M]<sup>+</sup>: 265.1911, found 265.1912

[α]<sub>D</sub><sup>20</sup>: +51.8° (c = 0.75, CHCl<sub>3</sub>)

#### (4*R*,4'*R*)-4,4'-dicyclohexyl-4,4',5,5'-tetrahydro-2,2'-bioxazole (BioxCy):

From *D*-cyclohexylglycine using General procedures A and B. BioxCy·HOTf was obtained as a colorless solid (2.91 g, 9.56 mmol, 72%).

<sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>): δ (ppm) 4.42 (dd, *J* = 9.8, 8.3 Hz, 2H), 4.14 (dd, *J* = 9.8, 8.3 Hz, 2H), 4.08 (td, *J* = 9.4, 6.7 Hz, 2H), 2.00-1.93 (m, 2H), 1.78-1.64 (m, 6H), 1.59-1.47 (m, 4H), 1.29-1.14 (m, 6H), 1.11-0.98 (m, 4H)

**General procedure D:** [Pd(IBioxR)( $\pi$ -allyl)Cl] complex synthesis

The [Pd(IBioxR)( $\pi$ -allyl)Cl] complexes were prepared according a procedure disclosed by Kündig.<sup>[114]</sup> In the glovebox, [Pd( $\pi$ -allyl)Cl]<sub>2</sub> (1.0 equiv.), **IBioxR·HOTf** (2.0 equiv.) and sodium *tert*-butoxide (2.0 equiv.) were placed into a dried catalysis tube. Dimethoxyethane (DME) (0.025 M, freshly distilled over Na and benzophenone) was added and the mixture was stirred at rt for 24 h and then quenched with aqueous NH<sub>4</sub>Cl and extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic phases were washed with water, brine, and dried over MgSO<sub>4</sub>. The resulting crude mixture was purified by flash column chromatography (EtOAc/pentane)

**[Pd(IBioxAd)( $\pi$ -allyl)Cl]:**

Using **IBioxAd·HOTf** (100 mg, 0.175 mmol, 2.0 equiv.) and Pd( $\pi$ -allyl)Cl]<sub>2</sub> (32.0 mg, 0.088 mmol, 1.0 equiv) following **general procedure D**, [Pd(IBioxAd)( $\pi$ -allyl)Cl] (82.0 mg, 0.136 mmol, 78%) was obtained as a colorless solid. As observed by <sup>1</sup>H NMR, this complex was obtained as a 1: 0.7 mixture of *endo*- and *exo*-isomers.

Description of major isomer:

**[Pd(IBioxAd)( $\pi$ -Allyl)Cl]**

### Synthesis of **IBioxfBuMe<sub>4</sub>**

### Methyl *N*-TFA *L*-tert-Leucinate (**S1**)

Under argon atmosphere, triethylamine (3.8 mL, 27.7 mmol, 3.0 equiv) was added to a solution of *L*-tert-Leucine methyl ester hydrochloride (1.68 g, 9.23 mmol, 1.0 equiv) in dry CH<sub>2</sub>Cl<sub>2</sub> (20 mL) and the reaction mixture was cooled to -78 °C. Trifluoroacetic anhydride (1.3 mL, 9.23 mmol, 1.0 equiv) was added dropwise over a period of 30 min and the solution was stirred at -78 °C for 3 h. The reaction mixture was quenched with sat. NaHCO<sub>3</sub> at -78 °C and was allowed to warm to room temperature. The aqueous phase was extracted with CH<sub>2</sub>Cl<sub>2</sub> (3 X 20 mL), the combined organic phase was washed with water, dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure affording the crude *N*-TFA *L*-tert-Leucine as a yellow oil (2.23 g, 9.23 mmol, quant.).

### 6.1.2 Substrates synthesis

#### General procedure E: benzylation of dimethyl malonate

Dimethyl malonate (1.4 equiv) was diluted in THF (1 mL/mmol of dimethyl malonate) and added to a suspension of 100% sodium hydride (1.2 equiv) in THF (1 mL/mmol of sodium hydride) and the mixture was stirred for 30 min at room temperature. Then, a solution of the benzyl bromide (1.0 equiv) in THF (2 mL/mmol of benzyl halide) was added dropwise and the mixture was stirred overnight at room temperature. The reaction was then quenched by addition of H<sub>2</sub>O and brine. The phases were separated, and the aqueous layer was extracted with diethyl ether. The combined organic phases were washed with brine and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the volatiles the crude mixture was purified by distillation under high vacuum to yield the corresponding dimethyl benzylmalonate.

#### Dimethyl 2-(2-bromo-4-fluorobenzyl)malonate (S4a):

From **dimethyl malonate** and **2-bromo-4-fluorobenzyl bromide** using **General procedure E**. **S4a** was obtained as a colorless solid (8.00 g, 25.08 mmol, 84%).

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.29 (dd, <sup>3</sup>J<sub>HF</sub> = 8.2, 2.6 Hz, 1H), 7.22 (dd, *J* = 8.6, 6.0 Hz, 1H), 6.94 (ddd, *J* = 8.2, 8.3, 2.6 Hz, 1H), 3.83 (t, *J* = 7.8 Hz, 1H), 3.70 (s, 6H) 3.31 (d, *J* = 7.8 Hz, 2H)

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 169.0, 161.6 (d, *J* = 250.2 Hz), 133.0 (d, *J* = 3.6 Hz), 132.4 (d, *J* = 8.3 Hz), 124.5 (d, *J* = 9.5 Hz), 120.3 (d, *J* = 24.4 Hz), 114.7 (d, *J* = 20.9 Hz), 52.8, 51.4, 34.5

**Rf**: 0.22 (pentane/EtOAc 95:5)

**General procedure F:** alkylation of dimethyl benzylmalonate

In a 10-20 mL microwave reaction vial, **S4** (1 equiv) was diluted in THF (3 mL/mmol of dimethyl benzylmalonate), then sodium hydride (60% in mineral oil, 1.2 equiv) was added in one portion and the mixture was stirred for 30 min at room temperature. Then, the choose alkyl halide (1.4 equiv) was added. If solid, the alkyl halide was added as a solution in THF. The vial was then sealed and transferred in an 80°C preheated aluminum block. After overnight stirring at this temperature, the reaction was quenched by addition of H<sub>2</sub>O and brine. The phases were separated, and the aqueous layer was extracted with diethyl ether or ethyl acetate. The combined organic phases were washed with brine and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the volatiles the crude mixture was purified by flash column chromatography (pentane/EtOAc) to yield the corresponding product **2.44**.

**General procedure G:** alkylation of dialkyl *n*-propylmalonate

In a 10-20 mL microwave reaction vial, dialkyl *n*-propylmalonate (1 equiv) was diluted in THF (3 mL/mmol of dimethyl *n*-propylmalonate), then sodium hydride (60% in mineral oil, 1.1 equiv) was added in one portion and the mixture was stirred for 30 min at room temperature. Then, the choose benzyl bromide (1.2 equiv) was added. If solid, the alkyl halide was added as a solution in THF. The vial was then sealed and transferred in an 80°C preheated aluminum block. After overnight stirring at this temperature, the reaction was quenched by addition of H<sub>2</sub>O and brine. The phases were separated, and the aqueous layer was extracted with diethyl ether or ethyl acetate. The combined organic phases were washed with brine and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the volatiles the crude product was purified by flash column chromatography (pentane/EtOAc) to yield the corresponding product **1**.

**Dimethyl 2-(2-bromo-4-fluorobenzyl)-2-propylmalonate (2.44a):**

From **S4a** and *n*-propyl iodide using **General procedure F**. **2.44a** was obtained as a colorless oil (842 mg, 2.42 mmol, 82%).

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.30-7.26 (m, 1H), 7.15 (dd,  $J = 8.7, 6.0$  Hz, 1H), 6.94 (ddd,  $J = 8.7, 7.8, 2.7$  Hz, 1H), 3.70 (s, 6H), 3.42 (s, 2H), 1.85-1.78 (m, 2H), 1.36-1.25 (m, 2H), 0.92 (t,  $J = 7.3$  Hz, 3H)

**1-(2,2-bis(Methoxymethyl)pentyl)-2-bromobenzene (2.44ag):**

DIBAL-H (8.52 g, 10.7 mmol, 6.1 eq.) was slowly added to a solution of dimethyl 2-(2-bromobenzyl)-2-propylmalonate (**2.44c-Br**) (600 mg, 1.75 mmol, 1.0 eq.) in dry CH<sub>2</sub>Cl<sub>2</sub> (11 mL) at 0°C. The mixture was stirred over night at 24 °C. The reaction was quenched by the addition of EtOAc at 0°C followed by H<sub>2</sub>O and HCl. The aqueous phase was extracted with EtOAc (3X 10 mL) and the combined organic layers were washed with brine and dried over Na<sub>2</sub>SO<sub>4</sub>. After evaporation of the volatiles, the crude product was added to a suspension of NaH (221 mg, 5.52 mmol, 3.0 eq.) in DMF (3.0 mL) at 0 °C. After stirring for 30 min, MeI (1.05 g, 7.36 mmol, 4.0 eq.) was added and the mixture was stirred overnight at 24 °C. The reaction was quenched with NH<sub>4</sub>Cl and extracted with EtOAc (3X 10 mL). The combined organic layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were evaporated under reduced pressure. After flash column chromatography (Cyclohexane:EtOAc, 90:10) the title compound (398 mg, 1.26 mmol, 69%) was obtained as a colorless oil.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.53 (dd, *J* = 8.1, 1.3 Hz, 1H), 7.29 (dd, *J* = 7.7, 1.8 Hz, 1H), 7.21 (td, *J* = 7.5, 1.3 Hz, 1H), 7.04 (td, *J* = 7.7, 1.8 Hz, 1H), 3.31 (s, 6H), 3.26 (d, *J* = 9.2 Hz, 2H), 3.17 (d, *J* = 9.2 Hz, 2H), 2.89 (s, 2H), 1.40 – 1.35 (m, 4H), 1.17 – 0.74 (m, 3H).

### 6.1.3 Enantioselective C(sp<sup>3</sup>)-H arylation

**General procedure H:** Representative procedure for the asymmetric C(sp<sup>3</sup>)-H arylation

In an 2-5 mL microwave reaction vial, substrate (0.2 mmol) was introduced. Then the tube was transferred in the glovebox and [Pd( $\pi$ -allyl)Cl]<sub>2</sub> (3.7 mg, 10  $\mu$ mol, 5 mol%), **IBioxAd•HOTf** (11.4 mg, 20  $\mu$ mol, 10 mol%), cesium pivalate (14 mg, 60  $\mu$ mol, 30 mol%), caesium carbonate (65 mg, 0.2 mmol, 1 equiv) and 5Å molecular sieves powder (50 mg) were introduced and the vial was then sealed. Outside of the glovebox,  $\alpha,\alpha,\alpha$ -trifluorotoluene (2 mL) was added. The reaction was stirred at room temperature for 10 min. The vial was then introduced in a 140°C preheated aluminum block and stirred at this temperature for 15 hours. After this period the reaction was cooled to room temperature, diluted with CH<sub>2</sub>Cl<sub>2</sub> (1.0 mL), filtered over a pad of Celite (washed three times with 1 mL of CH<sub>2</sub>Cl<sub>2</sub>). The crude material was analyzed by GC-MS and then concentrated and purified by preparative HPLC chromatography (EtOAc/hexane) to yield the corresponding indane product. Enantiomeric ratios were then determined by HPLC using a chiral stationary phase.

Racemic materials were obtained following the same procedure, using IBioxSpiCy•HOTf as ligand.

**Dimethyl (*R*)-1-ethyl-6-fluoro-1,3-dihydro-2*H*-indene-2,2-dicarboxylate (2.45a):**

From **2.44a** using **General procedure H**. **2.45a** was obtained as a colorless solid (48.2 mg, 0.172 mmol, 86%).

From **2.44a** (36.1 mg, 0.1mmol, 1.0 equiv) using **General procedure H** and **IBioxBuMe<sub>4</sub>** as the ligand. **2.45a** was obtained as a colorless oil (21.8 mg, 78.0  $\mu$ mol, 78%).

**[α]<sub>D</sub><sup>20</sup>**: -130.0° (c = 0.91, CHCl<sub>3</sub>)

**HPLC separation:** Chiralcel® OD-H; 99.5:0.5 (*n*-heptane/*i*-PrOH), 0.5 ml.min<sup>-1</sup>, 266 nm, *t*<sub>R</sub> (minor) = 13.2 min, *t*<sub>R</sub> (major) = 14.0 min, 98:2 e.r.

**Dimethyl (R)-1-(2-(1,3-dioxoisindolin-2-yl)ethyl)-6-fluoro-1,3-dihydro-2H-indene-2,2-dicarboxylate (2.45j):**

From **2.44j** using **General procedure H**, **2.45j** was obtained as a colorless oil (69.4 mg, 0.163 mmol, 82 %).

**2 mmol scale:** **2.44j** (1.01 g, 2.00 mmol, 1.0 equiv) was charged in a 100 mL ACE high pressure flask and the flask was transferred into the glovebox. Then, [Pd( $\pi$ -Allyl)Cl]<sub>2</sub> (37.3 mg, 0.100 mmol, 5 mol%), **IBioxAd·HOTf** (114 mg, 0.200 mmol, 10 mol%), cesium pivalate (140 mg, 0.600 mmol, 30 mol%), caesium carbonate (650 mg, 2.00 mmol, 1 equiv), 5 Å molecular sieves powder (500 mg) and  $\alpha,\alpha,\alpha$ -trifluorotoluene (20 mL) were added. Outside the glovebox the mixture was heated at 140 °C for 18 h. The reaction mixture was allowed to cool down to room temperature, filtered over a pad of celite and the volatiles were evaporated under reduced pressure. The crude solid residue recrystallized from EtOAc/*n*-hexane yielding **2.45j** (530 mg, 1.25 mmol, 62 %) as a colorless crystalline solid.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>):  $\delta$  (ppm) 7.88-7.82 (m, 2H), 7.74-7.69 (m, 2H), 7.16-7.10 (m, 2H), 6.88 (td, *J* = 8.7, 2.4 Hz, 1H), 3.94-3.86 (m, 2H), 3.79 (s, 3H), 3.78-3.74 (m, 1H), 3.71 (d, *J* = 16.3 Hz 1H), 3.69 (s, 3H), 3.28 (d, *J* = 16.3 Hz, 1H), 1.98-1.82 (m, 2H)

## Post-functionalizations

### Methyl (4a*R*,9a*R*)-6-fluoro-1-oxo-1,2,3,4,4a,9-hexahydro-9a*H*-indeno[2,1-*c*]pyridine-9a-carboxylate (**2.45ja**):

**2.45j** (24.6 mg, 0.06 mmol, 1.0 equiv) was dissolved in EtOH (1.0 mL) and hydrazine monohydrate (17.4 mg, 0.35 mmol, 6.0 equiv) was added. The mixture was heated to reflux for 3 h and stirred at room temperature overnight. The reaction mixture was then filtered and the solvent removed under reduced pressure. The residue was taken up in EtOAc (3.0 mL), washed with brine (3x 3.0 mL) and dried over Na<sub>2</sub>SO<sub>4</sub>. The solvent was removed under reduced pressure to give **2.45ja** (14.4 mg, 0.058 mmol, 95%) as a single diastereoisomer without further purification.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) δ 7.72 (s, 1H), 6.67-6.59 (m, 2H), 6.49 – 6.42 (m, 1H), 3.96 (d, *J* = 16.4, 1H), 3.48 (d, *J* = 16.4, 1H), 3.30 (s, 3H), 3.26 (t, *J* = 5.8, 1H), 2.66-2.60 (m, 1H), 2.52-2.45 (m, 1H), 1.75-1.67 (m, 1H), 1.22-1.14 (m, 1H)

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 172.3, 171.3, 162.8 (d, *J* = 243.4 Hz), 144.4 (d, *J* = 7.6 Hz), 136.7 (d, *J* = 2.5 Hz), 126.3 (d, *J* = 8.6 Hz), 114.7 (d, *J* = 22.4 Hz), 110.4 (d, *J* = 22.3 Hz), 60.8, 52.4, 47.8 (d, *J* = 2.1 Hz), 39.7, 39.2, 25.2

#### 6.1.4 Effect of the ligand structure on the enantioselectivity

##### Determination of buried volumes

DFT calculations were performed using Gaussian 16.<sup>[197]</sup> The geometries of [Pd(NHC)(allyl)Cl] complexes were optimized with the BP86<sup>[198,199]</sup> functional and TZVP basis set<sup>[200]</sup> for non-metal atoms and with a Stuttgart effective core potential and valence basis set<sup>[201,202]</sup> taken from the Basis Set Exchange<sup>[203]</sup> for Pd, similar to the method reported by Cavallo and co-workers.<sup>[156]</sup> Frequency calculations were performed to confirm the existence of a local minimum energy geometry.

The buried volumes of NHCs were determined using the SambVca 2.1 application<sup>[204]</sup> by inputting the above optimized structures of [Pd(NHC)(allyl)Cl] complexes. IMes and IAd were used as reference NHC ligands to validate the method (calculated % *V*<sub>Bur</sub> from DFT-optimized complexes: IMes, 32.7, IAd, 37.3, calculated % *V*<sub>Bur</sub> from Xray structures: IMes, 32.6, IAd, 37.5).<sup>[205]</sup>

The enantiomeric ratio was obtained by HPLC analysis on a chiral stationary phase.

IBioxR	e.r.	% <i>V</i> <sub>Bur</sub> (3.5 Å)	Quadrant Diff % <i>V</i> <sub>Bur</sub> [% <i>V</i> <sub>Bur</sub> (SW+NE)–% <i>V</i> <sub>Bur</sub> (NW+SE)]/2
Menth	6.1	43.5	1.4
<i>i</i> Pr	5.7	30.1	14.05
<i>t</i> Bu	13.3	30.1	14.1
Cy	49.0	34.2	22.25
Ad	49.0	34.5	22.25
<i>t</i> BuMe <sub>4</sub>	165.7	34.7	23

**Table S1:** Effect of ligand structure on enantioselectivity. Calculated % *V*<sub>Bur</sub> and Quadrant Diff % *V*<sub>Bur</sub>

#### 6.1.5 Determination of absolute configuration of **2.45c**, **2.45t** and **2.45ja** by VCD spectroscopy

##### VCD experiments

IR and vibrational circular dichroism (VCD) spectra were recorded on a Bruker PMA 50 accessory coupled to a Tensor 27 Fourier transform infrared spectrometer. A photoelastic modulator (Hinds PEM 90) set at 1/4 retardation was used to modulate the handedness of the circular polarized light. Demodulation was performed by a lock-in amplifier (SR830 DSP). An optical low-pass filter ( $< 1800\text{ cm}^{-1}$ ) in front of the photoelastic modulator was used to enhance the signal/noise ratio. Solutions of ca. 4 mg in 200  $\mu\text{l}$   $\text{CD}_2\text{Cl}_2$  of **2.45c**, **2.45t** and **2.45ja** were prepared and measured in a transmission cell equipped with  $\text{CaF}_2$  windows and a 200  $\mu\text{m}$  spacer. The VCD spectrum of the pure solvent served as the reference and was subtracted from the VCD spectrum of the compound in order to eliminate artefacts. For both the sample and the reference, ca. 30'000 scans at  $4\text{ cm}^{-1}$  resolution were averaged.

##### Calculations

Density functional theory (DFT) as implemented in Gaussian16<sup>[197]</sup> was used to study the conformation and to calculate the corresponding IR and VCD spectra. The calculations were performed using the b3pw91 functional and a 6-31+G(d,p) basis set. All calculations were performed for gas phase species. Prior to the calculation of the spectra all degrees of freedom were completely relaxed. IR and VCD spectra were constructed from calculated dipole and rotational strengths assuming Gaussian band shape with a half-width at half-maximum of  $4\text{ cm}^{-1}$ . Frequencies were scaled by a factor of 0.97. To calculate the Boltzmann distribution of the different conformers a thermal free energy correction was applied. Only conformers with a population of at least 4% were considered.

##### Conformational search

A systematic conformation search was done taking into account the conformational degrees of freedom of the respective molecules. For **2.45c** the 5-ring is not flat. In addition the orientation of the ester groups and the ethyl group has to be considered. Similarly, for **2.45t** the conformation of the 5-ring, the orientation of the ester groups and the orientation of the amide group had to be considered. For **2.45ja** the conformation degrees of freedom that were considered are the 5-ring, the 6-ring (position of  $\text{CH}_2$  group) and the orientation of the ester group.

## Results for 2.45c

**Figure S1:** The structure shows the most stable conformer of **2.45c** found. This conformer accounts for 58% according to a Boltzmann population at room temperature.

**Figure S2:** Calculated IR spectra of the five most stable conformers of **2.45c** accounting for (from bottom to top) 5%, 10%, 58%, 20% and 7% of the calculated population.

**Figure S3:** Calculated VCD spectra of the five most stable conformers of **2.45c** accounting for (from bottom to top) 5%, 10%, 58%, 20% and 7% of the calculated population.

**Figure S4:** Comparison between experimental (black) and calculated (red) infrared spectra of **2.45c**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the five most stable conformers.

**Figure S5:** Comparison between experimental (black) and calculated (red) VCD spectra of **2.45c**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the five most stable conformers.

#### *Assignment of absolute configuration*

Except for the carbonyl region the agreement between experimental and calculated VCD spectra is good. The absolute configuration of the sample measured and the one used for the calculation (see structure above) is therefore the same.

Results for 2.45t

**Figure S6:** The structure shows the most stable conformer of **2.45t** found. This conformer accounts for 48% according to a Boltzmann population at room temperature.

**Figure S7:** Calculated IR spectra of the three most stable conformers of **2.45t** accounting for (from bottom to top) 48%, 4% and 48% of the calculated population.

**Figure S8:** Calculated VCD spectra of the three most stable conformers of **2.45t** accounting for (from bottom to top) 48%, 4% and 48% of the calculated population.

**Figure S9:** Comparison between experimental (black) and calculated (red) infrared spectra of **2.45t**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the three most stable conformers.

**Figure S10:** Comparison between experimental (black) and calculated (red) VCD spectra of **2.45t**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the three most stable conformers.

#### *Assignment of absolute configuration*

Except for the carbonyl region the agreement between experimental and calculated VCD spectra is good. The absolute configuration of the sample measured and the one used for the calculation (see structure above) is therefore the same.

## Results for 2.45ja

**Figure S.11:** The structure shows the most stable conformer of **2.45ja** found. This conformer accounts for 42% according to a Boltzmann population at room temperature.

**Figure S15:** Calculated IR spectra of the five most stable conformers of **2.45ja** accounting for (from bottom to top) 17%, 7%, 42%, 11% and 23% of the calculated population.

**Figure S13:** Calculated VCD spectra of the five most stable conformers of **2.45ja** accounting for (from bottom to top) 17%, 7%, 42%, 11% and 23% of the calculated population.

**Figure S14:** Comparison between experimental (black) and calculated (red) infrared spectra of **2.45ja**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the five most stable conformers.

**Figure S15:** Comparison between experimental (black) and calculated (red) VCD spectra of **2.45ja**. The calculated spectrum is the linear combination (Boltzmann weighted) of the spectra of the five most stable conformers.

#### *Assignment of absolute configuration*

Except for the carbonyl region the agreement between experimental and calculated VCD spectra is good. The absolute configuration of the sample measured and the one used for the calculation (see structure above) is therefore the same.

## 6.1.6 Synthesis of new substrates for enantioselective C(sp<sup>3</sup>)-H activation

### 2-Bromo-*N,N*-diethylbenzenesulfonamide (2.62):

2-Bromobenzenesulfonyl chloride (1.00 g, 3.91 mmol, 1.0 eq.) and diethyl amine (372 mg, 5.08 mmol, 1.30 eq.) were dissolved in CH<sub>2</sub>Cl<sub>2</sub> (10 mL). Triethyl amine (1.20 g, 11.7 mmol, 3.0 eq.) was added and the reaction was stirred for 3 h. The reaction was quenched by the addition of H<sub>2</sub>O (10 mL) and the aqueous phase was extracted with EtOAc (3 x 10 mL). The combined organic layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were evaporated under reduced pressure. The title compound was obtained as a colorless oil (837 mg, 2.86 mmol, 73%) without further purification.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 8.13 (d, *J* = 7.8 Hz, 1H), 7.72 (d, *J* = 7.8 Hz, 1H), 7.49 – 7.31 (m, 2H), 3.39 (q, *J* = 7.1 Hz, 4H), 1.12 (t, *J* = 7.1 Hz, 6H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 140.0, 135.7, 133.4, 132.3, 127.6, 120.5, 41.3, 13.8.

**GC-MS** (EI): Calcd for C<sub>10</sub>H<sub>14</sub><sup>79</sup>BrNO<sub>2</sub>S [M]<sup>+</sup>: 291, found 291

### 2-Bromo-*N,N*-diethylbenzamide (2.63):

2-Bromobenzoyl chloride (3.00 g, 13.7 mmol, 1.0 eq.) and diethylamine (1.10 g, 15.0 mmol, 1.1 eq.) were dissolved in CH<sub>2</sub>Cl<sub>2</sub> (75 mL). Triethylamine (1.73 g, 17.1 mmol, 1.25 eq.) was added and the reaction was stirred for 3 h. The reaction was quenched by the addition of H<sub>2</sub>O (10 mL) and the aqueous phase was extracted with EtOAc (3 x 10 mL). The combined organic layers were washed with brine, dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were evaporated under reduced pressure. The title compound was obtained as a colorless oil (3.30 g, 12.9 mmol, 94%). Without further purification.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.56 (d, *J* = 8.1 Hz, 1H), 7.37 – 7.30 (m, 1H), 7.29 – 7.14 (m, 2H), 3.83 (dq, *J* = 14.6, 7.4 Hz, 1H), 3.34 (dq, *J* = 14.4, 7.3 Hz, 1H), 3.15 (dq, *J* = 16.1, 8.4, 8.0 Hz, 2H), 1.27 (t, *J* = 7.1 Hz, 3H), 1.06 (t, *J* = 7.1 Hz, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 168.6, 139.0, 132.9, 130.1, 127.7, 127.6, 119.4, 42.8,

39.1, 14.0, 12.7.

**GC-MS** (EI): Calcd for C<sub>11</sub>H<sub>14</sub><sup>79</sup>BrNO [M]<sup>+</sup>: 255, found 255

### Dimethyl 2-(2'-bromo-[1,1'-biphenyl]-2-yl)-2-ethylmalonate (2.64):

According to **general procedure F**, dimethyl 2-(2'-bromo-[1,1'-biphenyl]-2-yl)malonate (476 mg, 1.31 mmol, 1.0 eq.) was reacted with ethyl iodide (245 mg, 1.57 mmol, 1.2 eq.) to give the title compound (350 mg, 895 μmol, 68%) as a yellow oil.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.55 (d, *J* = 8.0 Hz, 1H), 7.25 – 7.04 (m, 6H), 6.99 (d, *J* = 7.6 Hz, 1H), 3.60 (s, 3H), 3.36 (s, 3H), 2.10 (dq, *J* = 14.5, 7.3 Hz, 1H), 1.92 (dq, *J* = 14.5, 7.3 Hz, 1H), 0.78 (t, *J* = 7.3 Hz, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 171.5, 170.9, 142.0, 139.9, 136.25, 133.2, 132.9, 131.7, 129.8, 129.2, 127.8, 127.0, 126.6, 124.9, 64.2, 52.7, 52.7, 29.8, 10.6.

**GC-MS** (EI): Calcd for C<sub>19</sub>H<sub>19</sub><sup>79</sup>BrO<sub>4</sub> [M]<sup>+</sup>: 390, found 390

**Dimethyl 2-((2'-bromo-[1,1'-biphenyl]-2-yl)methyl)-2-propylmalonate (2.65):**

According to **general procedure G**, dimethyl 2-propylmalonate (557 mg, 3.20 mmol, 1.0 eq.) was reacted with 2-bromo-2'-(bromomethyl)-1,1'-biphenyl (1.25 g, 3.83 mmol, 1.2 eq.) to give the title compound (1.00 g, 2.38 mmol, 73 %) as a brown oil.

**$^1\text{H}$  NMR** (500 MHz,  $\text{CDCl}_3$ ):  $\delta$  (ppm) 7.65 (d,  $J = 8.0$  Hz, 1H), 7.43 – 7.26 (m, 3H), 7.24 – 7.16 (m, 2H), 7.17 – 7.07 (m, 2H), 3.66 (s, 3H), 3.64 (s, 3H), 3.38 (d,  $J = 14.7$  Hz, 1H), 3.17 – 3.08 (m, 1H), 1.65 – 1.56 (m, 1H), 1.54 – 1.45 (m, 1H), 0.69 (t,  $J = 4.8$  Hz, 3H).

**$^{13}\text{C}$  NMR** (126 MHz,  $\text{CDCl}_3$ ):  $\delta$  (ppm) 172.2, 172.1, 134.5, 133.0, 132., 130.78, 129.7, 128.9, 128.0, 127.3, 126.7, 124.2, 59.3, 52.4, 52.3, 35.1, 34.5, 17.7, 14.4.

**GC-MS** (EI): Calcd for  $C_{21}H_{23}^{79}\text{BrO}_4$   $[M]^+$ : 418, found 418

**Dimethyl 2-(2-bromophenyl)-2-(2-(dimethylamino)-2-oxoethyl)malonateglycinate (2.66a):**

According to **general procedure F**, dimethyl 2-(2-bromophenyl)malonate (502 mg, 1.76 mmol, 1.0 eq.) was reacted with 2-chloro-*N,N*-dimethylacetamide (300 mg, 2.46 mmol, 1.4 eq.) to give the title compound (353 mg, 947  $\mu\text{mol}$ , 54%) as a colorless oil.

**$^1\text{H}$  NMR** (500 MHz,  $\text{CDCl}_3$ ): 7.60 (dd,  $J = 8.1, 1.6$  Hz, 1H), 7.56 (dd,  $J = 8.1, 1.4$  Hz, 1H), 7.31 (td,  $J = 7.8, 1.4$  Hz, 1H), 7.15 (td,  $J = 7.8, 1.6$  Hz, 1H), 3.82 (s, 6H), 3.53 (s, 2H), 3.03 (s, 3H), 2.93 (s, 3H).

**$^{13}\text{C}$  NMR** (126 MHz,  $\text{CDCl}_3$ ):  $\delta$  (ppm) 170.1, 169.6, 137.3, 134.7, 131.4, 129.3, 127.6, 123.3, 63.0, 53.5, 38.8, 37.4, 35.8.

**GC-MS** (EI): Calcd for  $C_{17}H_{21}^{79}\text{BrO}_6$   $[M]^+$ : 371, found 371

**Trimethyl 1-(2-bromophenyl)ethane-1,1,2-tricarboxylate (2.66b):**

According to **general procedure F**, dimethyl 2-(2-bromophenyl)malonate (1.00 g, 3.48 mmol, 1.0 eq.) was reacted with methyl 2-bromoacetate (639 mg, 4.17 mmol, 1.2 eq.) to give the title compound (620 mg, 1.73 mmol, 50%) as a yellow oil.

**$^1\text{H}$  NMR** (500 MHz,  $\text{CDCl}_3$ ): 7.58 (dd,  $J = 7.9, 1.4$  Hz, 1H), 7.38 – 7.29 (m, 2H), 7.23 – 7.13 (m, 1H), 3.84 (s, 6H), 3.69 (s, 3H), 3.48 (s, 2H).

**$^{13}\text{C}$  NMR** (126 MHz,  $\text{CDCl}_3$ ):  $\delta$  (ppm) 170.9, 169.7, 136.5, 135.0, 130.5, 129.6, 127.7, 123.3, 63.2, 53.6, 52.1, 39.3.

**GC-MS** (EI): Calcd for  $C_{14}H_{15}^{79}\text{BrO}_6$   $[M]^+$ : 358, found 358

**Tert-butyl N-(2-bromobenzyl)-N-(2,2,2-trifluoroacetyl)glycinate (2.68a):**

Titanium(IV) isopropoxide (2.11, 7.13 mmol, 1.3 eq.) was added to a solution of tert-butyl glycinate (1.42 g, 10.8 mmol, 2.0 eq.) followed by the addition of 2-bromobenzaldehyde (1.00 g, 5.40 mmol, 1.0 eq.). The reaction mixture was stirred for 3 h at 24 °C. Then, Sodium borohydride (204 mg, 5.40 mmol, 1.0 eq.) was added and the mixture was stirred for another 2 h. The reaction was quenched by the addition of  $\text{H}_2\text{O}$  (2.0 mL) and the precipitate was filtered and washed with diethyl ether (20 mL). The organic layer was separated and the aqueous phase was

extracted with diethyl ether (20 mL). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were removed under reduced pressure. The crude product was then dissolved in CH<sub>2</sub>Cl<sub>2</sub> (11 mL) and Et<sub>3</sub>N (318 mg, 3.14 mmol, 1.4 eq.), DMAP (26.6 mg, 218 μmol, 0.1 eq.) and trifluoroacetic anhydride (549 mg, 2.62 mmol 1.2 eq.) were added at 0 °C. The mixture was stirred for 16 at 24 °C and the volatiles were removed under reduced pressure. Purification by flash column chromatography (Cyclohexane:EtOAc, 85:15) yield the title compound (800 mg, 2.02 mmol, 93%) as a yellow liquid.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.61 – 7.51 (m, 1H), 7.38 – 7.29 (m, 1H), 7.28 – 7.25 (m, 1H), 7.25 – 7.17 (m, 1H), 4.84 (d, *J* = 26.6 Hz, 2H), 3.94 (d, *J* = 32.7 Hz, 2H), 1.46 (s, 9H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 166.85, 166.34, 157.91 (dq, *J* = 48.9, 36.5 Hz), 133.92 (d, *J* = 56.1 Hz), 133.37 (d, *J* = 16.0 Hz), 130.59, 130.01 (d, *J* = 5.3 Hz), 128.68, 128.21 (d, *J* = 2.3 Hz), 124.00 (d, *J* = 112.9 Hz), 121.95 – 111.27 (m), 83.10 (d, *J* = 39.3 Hz), 51.72 (q, *J* = 3.6 Hz), 50.92, 48.53 (q, *J* = 3.5 Hz), 28.04 (d, *J* = 11.2 Hz).

**GC-MS** (EI): Calcd for C<sub>15</sub>H<sub>17</sub><sup>79</sup>BrF<sub>3</sub>NO<sub>3</sub> [M]<sup>+</sup>: 395, found 395

#### Methyl N-((3*r*,5*r*,7*r*)-adamantane-1-carbonyl)-N-(2-bromobenzyl)glycinate (**2.68b**):

Titanium(IV) isopropoxide (2.11, 7.13 mmol, 1.3 eq.) was added to a solution of methyl glycinate (962 mg, 10.8 mmol, 2.0 eq.) followed by the addition of 2-bromobenzaldehyde (1.00 g, 5.40 mmol, 1.0 eq.). The reaction mixture was stirred for 3 h at 24 °C. Then, Sodium borohydride (204 mg, 5.40 mmol, 1.0 eq.) was added and the mixture was stirred for another 2 h. The reaction was quenched by the addition of H<sub>2</sub>O (2.0 mL) and the precipitate was filtered and washed with diethyl ether (20 mL). The organic layer was separated and the aqueous phase was extracted with diethyl ether (20 mL). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were removed under reduced pressure. The crude product was then dissolved in CH<sub>2</sub>Cl<sub>2</sub> (11 mL) and Et<sub>3</sub>N (318 mg, 3.14 mmol, 1.4 eq.), DMAP (26.6 mg, 218 μmol, 0.1 eq.) and adamantane-1-carbonyl chloride (1.29 g, 6.48 mmol 1.2 eq.) were added at 0 °C. The mixture was stirred for 16 at 24 °C and the volatiles were removed under reduced pressure. Purification by flash column chromatography (Cyclohexane:EtOAc, 85:15) yield the title compound (662 mg, 1.57 mmol, 29%) as a yellow liquid.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.57 (d, *J* = 7.8 Hz, 1H), 7.33 (t, *J* = 7.5 Hz, 1H), 7.22 – 7.12 (m, 2H), 4.90 (s, 2H), 3.93 (s, 2H), 3.73 (s, 3H), 2.00 (s, 9H), 1.74 – 1.61 (m, 6H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 178.3, 170.2, 136.1, 133.2, 129.1, 127.9, 122.9, 53.4, 52.2, 50.1, 42.1, 39.2, 36.6, 28.5.

**GC-MS** (EI): Calcd for C<sub>21</sub>H<sub>26</sub><sup>79</sup>BrNO<sub>3</sub> [M]<sup>+</sup>: 419, found 419

### N-(2-bromobenzyl)-4-methyl-N-propylbenzenesulfonamide (2.71):

of 2-bromobenzaldehyde (2.00 g, 9.85 mmol, 1.00 eq.) was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (20 mL) and *n*-propylamine (640 mg, 10.8 mmol, 1.1 eq.) and Na<sub>2</sub>SO<sub>4</sub> (4.20 g, 29.6 mmol, 3.0 eq.) was added. The mixture was stirred at roomtemperature for 3 h and sodium borohydride (186 mg, 4.93 mmol, 0.5 eq) was added. The reaction mixture was stirred for another 2 h before quenching with H<sub>2</sub>O (2.0 mL). The aqueous phase was extracted with EtOAc (3X 20 mL) and the combined organic layers were washed with H<sub>2</sub>O (20 mL) and brine (20 mL). The organic phase was dried over Na<sub>2</sub>SO<sub>4</sub> and the volatiles were removed under reduced pressure. The crude mixture was dissolved again in CH<sub>2</sub>Cl<sub>2</sub> (20 mL) and DMAP (120 mg, 985 μmol, 0.1 eq), DIPEA (3.82 g, 29.6 mmol, 3.0 eq.) and *p*-toluenesulfonyl chloride (2.82 g, 14.8 mmol, 1.5 eq.) were added. The reaction was stirred for 2 h at 24 °C and the volatiles were then removed under reduced pressure. Flash column chromatography (cyclohexane:EtOAc, 80:20) gave the title compound (1.75 g, 4.45 mmol, 45%) as colorless oil.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): 7.78 – 7.70 (m, 1H), 7.62 – 7.57 (m, 1H), 7.52 – 7.47 (m, 1H), 7.35 – 7.28 (m, 3H), 7.16 – 7.11 (m, 1H), 4.43 (s, 2H), 3.11 (dd, *J* = 9.0, 6.7 Hz, 2H), 2.44 (s, 3H), 1.43 – 1.31 (m, 2H), 0.74 (t, *J* = 7.4 Hz, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 143.5, 137.1, 136.3, 132.7, 130.2, 129.1, 127.8, 127.3, 123.0, 51.9, 51.1, 21.7, 11.3.

**GC-MS** (EI): Calcd for C<sub>17</sub>H<sub>20</sub><sup>79</sup>BrNO<sub>2</sub>S [M]<sup>+</sup>: 381, found 381

## 6.2 The effect of $\alpha$ -substitution on the reactivity of Pd(0)-catalyzed C(sp<sup>3</sup>)-H activation for the formation of indanes

### 6.2.1 Catalyst preparation

#### <sup>t</sup>BuIndPd(IBiox6)Cl (**3.19**):

**3.19**  
C<sub>30</sub>H<sub>40</sub>ClN<sub>2</sub>O<sub>2</sub>Pd  
M = 602,53 g·mol<sup>-1</sup>

The title compound (**10**) was prepared after a modified procedure from Kündig.<sup>[114]</sup> In the glovebox a schlenktube was charged with [<sup>t</sup>BuIndPdCl]<sub>2</sub> (1.07 g, 1.71 mmol, 1.0 eq.) IBiox6.HOTf (1.50 g, 3.42 mmol, 2.0 equiv) and NaOtBu (329 mg, 3.42 mmol, 2.0 equiv) and sealed with a rubber septum. Outside the glovebox, 1,2-dimethoxyethan (70 mL) was added and the reaction was stirred at 24 °C for 18 h. The reaction was quenched with aq. NH<sub>4</sub>Cl and extracted with CH<sub>2</sub>Cl<sub>2</sub>. The combined organic layers were washed with brine, dried over and evaporated under reduced pressure. The crude mixture was purified by column chromatography (cyclohexane:EtOAc, 80:20) to obtain a deep red slurry which was triturated in a diethyl ether/pentane mixture to obtain product **10** (1.25 g, 2.08 mmol, 61%) as bright yellow solid.

**<sup>1</sup>H NMR** (500 MHz, C<sub>6</sub>D<sub>6</sub>):  $\delta$  (ppm) 7.52 (dd,  $J$  = 7.7, 0.9 Hz, 1H), 6.98 (dt,  $J$  = 7.7, 4.3 Hz, 1H), 6.81 (d,  $J$  = 4.2 Hz, 2H), 6.64 (d,  $J$  = 2.8 Hz, 1H), 5.08 (d,  $J$  = 2.8 Hz, 1H), 4.03 – 3.99 (m, 3H), 3.96 (d,  $J$  = 8.5 Hz, 1H), 3.17 (td,  $J$  = 14.0, 4.1 Hz, 1H), 2.77 (td,  $J$  = 13.9, 4.1 Hz, 1H), 2.13 (td,  $J$  = 13.6, 12.9, 4.4 Hz, 1H), 1.88 – 1.83 (m, 1H), 1.83 – 1.77 (m, 2H), 1.73 (s, 9H), 1.51 – 1.41 (m, 5 H), 1.39 – 1.31 (m, 2H), 1.26 (td,  $J$  = 7.6, 6.9, 3.6 Hz, 1H), 1.23 – 1.17 (m, 1H), 1.10 (qt,  $J$  = 13.4, 3.6 Hz, 1H), 0.96 – 0.83 (m, 1H), 0.72 – 0.62 (m, 2H), 0.60 – 0.52 (m, 1H), 0.51 – 0.40 (m, 1H).

**<sup>13</sup>C NMR** (126 MHz, C<sub>6</sub>D<sub>6</sub>):  $\delta$  (ppm) 141.5, 141.3, 139.3, 126.5, 126.2, 124.8, 124.0, 120.8, 117.8, 116.7, 109.6, 84.4, 84.3, 65.1, 64.1, 163.1, 36.3, 35.6, 35.1, 35.0, 34.5, 29.9, 25.4, 24.2, 24.0, 24.0, 23.7, 23.4.

### 6.2.3 Product syntheses

**General procedure H:** Synthesis of indane products by  $\text{Pd}(0)$ -catalyzed  $\text{C}(\text{sp}^3)\text{-H}$  activation of methylene  $\text{C-H}$  bonds.

In an 2-5 mL microwave reaction vial, substrate (0.2 mmol) was introduced. Then the tube was transferred in the glovebox and  $[\text{Pd}(\pi\text{-allyl})\text{Cl}]_2$  (3.7 mg, 10  $\mu\text{mol}$ , 5 mol%), IBiox6·HOTf (11.4 mg, 20  $\mu\text{mol}$ , 10 mol%), cesium pivalate (14 mg, 60  $\mu\text{mol}$ , 30 mol%), caesium carbonate (65 mg, 0.2 mmol, 1 equiv) and 5 Å molecular sieves powder (50 mg) were introduced and the vial was then sealed. Outside of the glovebox,  $\alpha,\alpha,\alpha$ -trifluorotoluene (2 mL) was added. The reaction was stirred at room temperature for 10 min. The vial was then introduced in a 140°C preheated aluminum block and stirred at this temperature for 15 hours. After this period the reaction was cooled to room temperature, diluted with  $\text{CH}_2\text{Cl}_2$  (1.0 mL), filtered over a pad of Celite (washed three times with 1 mL of  $\text{CH}_2\text{Cl}_2$ ). The crude material was analyzed by GC-MS and then concentrated and purified by preparative HPLC chromatography (EtOAc/hexane) to yield the corresponding indane product.

**Dimethyl 6-fluoro-1-methyl-1,3-dihydro-2H-indene-2,2-dicarboxylate (2.45ah):**

According to **general procedure H** the title compound (27.0 mg, 101  $\mu$ mol, 51%) was obtained as a colorless oil.

**$^1H$  NMR** (500 MHz,  $CDCl_3$ ):  $\delta$  (ppm) 7.10 (dd,  $J = 9.0, 5.1$  Hz, 1H), 6.89 – 6.80 (m, 2H), 4.00 (q,  $J = 7.2$  Hz, 1H), 3.74 (s, 3H), 3.73 (s, 3H), 3.70 (d,  $J = 16.2$  Hz, 1H), 3.25 (d,  $J = 16.2$  Hz, 1H), 1.22 (d,  $J = 7.2$  Hz, 3H).

**Dimethyl 6-fluoro-1-phenyl-1,3-dihydro-2*H*-indene-2,2-dicarboxylate (2.45ao):**

Under Ar atmosphere at 0 °C dimethyl malonate (291 mg, 2.2 mmol, 1.1 eq.) was added to a suspension of NaH (264 mg, 60%, 6.60 mmol, 3.3 eq.) in THF (10 mL). After stirring for 30 min a solution of 2-(bromo(phenyl)methyl)-1-(bromomethyl)-4-fluorobenzene (715 mg, 2.00 mmol, 1.0 eq.) in THF (6.0 mL) was added. The reaction was heated to reflux for 16 h and then quenched by the addition of H<sub>2</sub>O. The layers were separated and the aqueous phase was extracted with Et<sub>2</sub>O (3 x 15 mL). The combined organic layers were dried over Na<sub>2</sub>SO<sub>4</sub> and concentrated under reduced pressure. The crude product was purified by flash column chromatography (cyclohexane/EtOAc 90:10) to obtain the title compound (360 mg, 1.10 mmol, 55 %) as a colorless solid.

**<sup>1</sup>H NMR** (250 MHz, CDCl<sub>3</sub>): δ (ppm) 7.25 – 7.19 (m, 4H), 7.11 – 7.01 (m, 2H), 6.96 – 6.89 (m, 1H), 6.73 (dd, *J* = 8.8, 2.5 Hz, 1H), 5.33 (s, 1H), 3.97 (d, *J* = 16.6 Hz, 1H), 3.76 (s, 3H), 3.32 (d, *J* = 16.6 Hz, 1H), 3.21 (s, 3H).

## 6.2.4 Kinetic experiments

### General procedure I

Inside a glovebox, CsOPiv (14.0 mg, 60  $\mu\text{mol}$ , 0.3 eq.) and Cs<sub>2</sub>CO<sub>3</sub> (65.2 mg, 0.2 mmol, 1.0 eq) were weighted 7 times and charged in 7 different catalysis tubes individually. Stock solutions of  $[\text{Pd}(\text{tBuInd})(\text{IBiox}_6)\text{Cl}]$  (20  $\mu\text{mol}/\text{mL}$ ) and substrate (200  $\mu\text{mol}/\text{mL}$ ) in CF<sub>3</sub>Ph were prepared and 1 mL of each was added in each tube to reach a concentration of 0.1 M. The tubes were capped, taken out of the glovebox and inserted in a preheated metal block at 140 °C with a stirring rate of 1000 rpm. The reactions were stopped at different times and cooled to 24 °C by inserting the tubes into another metal block. A stock solution of the internal standard (200  $\mu\text{mol}/\text{mL}$ ) in CF<sub>3</sub>Ph was prepared and 1 mL was added to each tube after the reaction. The mixture was filtered over a short pad of silica and analysed by <sup>19</sup>F NMR against the standard.

### Orders by VTNA

Order on Aryl bromide

The reaction displays zero order with respect to the concentration of aryl bromide starting material. This suggests that the oxidative addition is not kinetically relevant in this reaction.

## Order on catalyst

Clockwise from top left: Order 1 on catalyst, Order 0.5 on catalyst, Order 0 on catalyst. The curves overlay when the power is raised to 1, suggesting 1<sup>st</sup> order dependence on the concentration of catalyst for this reaction.

### Order on Cs<sub>2</sub>CO<sub>3</sub>

The reaction displays zero order with respect to the concentration of Cs<sub>2</sub>CO<sub>3</sub>. However, this is most likely as a result of saturation kinetics being observed for this inorganic base in a PhCF<sub>3</sub>.

### Order on CsOPiv

The reaction displays zero order with respect to the concentration of CsOPiv. This could suggest that the pivalate is not engaged in the C–H activation step, however due to the low solubility of CsOPiv in PhCF<sub>3</sub>, it is not possible with this data to rule out the observation of zero order kinetics due to saturation.

### Reaction at different stirring rates

The reaction displays significant variation when the stirring rate is altered. This suggests that one of the inorganic bases in the reaction (or both) are involved in a kinetically relevant step

### Reaction without Cs<sub>2</sub>CO<sub>3</sub>

The reaction failed to give any product formation in the absence of Cs<sub>2</sub>CO<sub>3</sub>. Only the corresponding protodehalogenated starting material was detected.

### Reaction without CsOPiv

The reaction failed to give any product formation in the absence of CsOPiv. Only the corresponding protodehalogenated starting material was detected

## General procedure J

Inside a glovebox, CsOPiv (14.0 mg, 60  $\mu\text{mol}$ , 0.3 eq.) and  $\text{Cs}_2\text{CO}_3$  (65.2 mg, 0.2 mmol, 1.0 eq) were weighted 7 times and charged in 7 different catalysis tubes individually. Stock solutions of  $[\text{Pd}^{\text{(tBu)}}\text{Ind}^{\text{(IBiox}_6\text{)Cl}}]$  (20  $\mu\text{mol/mL}$ ) and substrate (200  $\mu\text{mol/mL}$ ) in  $\text{CF}_3\text{Ph}$  were prepared and 1 mL of each was added in each tube to reach a concentration of 0.1 M. The tubes were capped, taken out of the glovebox and inserted in a preheated metal block at 140  $^\circ\text{C}$ . The reactions were stopped at different times and immediately cooled to 24  $^\circ\text{C}$  by inserting the tubes into another metal block. A stock solution of the external standard (200  $\mu\text{mol/mL}$ ) in  $\text{CF}_3\text{Ph}$  was prepared and 1 mL was added to each tube after the reaction. The mixture was filtered over a short pad of silica and analysed by  $^{19}\text{F}$  NMR against the standard.

## 6.3 Enantioselective remote C(sp<sup>3</sup>)-H activation by 1,4-Pd shift

### 6.3.1 Substrate synthesis

#### 2-(3-Bromo-2-methoxyphenyl)-*N,N*-dimethylacetamide (4.16a):

The title compound (1.04 g, 3.82 mmol, 47%) was obtained following a literature procedure from 2-(3-bromo-2-methoxyphenyl)acetic acid (2.0 g, 8.16 mmol, 1.0 eq.) and dimethylamine hydrochloride (732 mg, 8.98 mmol, 1.10 eq.).<sup>[185]</sup>

<sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.45 (dd, *J* = 7.9, 1.6 Hz, 1H), 7.21 (dd, *J* = 7.7, 1.6 Hz, 1H), 6.95 (t, *J* = 7.8 Hz, 1H), 3.82 (s, 3H), 3.75 (s, 2H), 3.01 (s, 3H), 2.97 (s, 3H).

<sup>13</sup>C NMR (126 MHz, CDCl<sub>3</sub>): δ (ppm) 170.8, 155.0, 132.5, 131.0, 129.9, 125.7, 117.3, 61.1, 37.7, 35.8, 35.2.

GC-MS (EI): Calcd for C<sub>11</sub>H<sub>14</sub><sup>79</sup>BrNO<sub>2</sub> [M]<sup>+</sup>: 271, found 271

#### 3-Bromo-2-methoxybenzyl pivalate (4.16b):

3-bromo-2-methoxybenzaldehyde (900 mg, 4.19 mmol, 1.0 eq.) was dissolved in MeOH (14 mL) and NaBH<sub>4</sub> (238 mg, 6.29 mmol, 1.5 eq.) was added portion wise at 0 °C. The reaction mixture was stirred at 24 °C for 3 h and quenched by the addition of H<sub>2</sub>O (5.0 mL). The aqueous phase was extracted with EtOAc and the combined organic layers were washed with H<sub>2</sub>O (15 mL), Brine (15 mL) and dried over Na<sub>2</sub>SO<sub>4</sub>. Afterwards the volatiles were removed under reduced pressure. The crude benzyl alcohol was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (8.0 mL) and pyridine (251 mg, 3.17 mmol, 0.80 eq.) and pivalyl chloride (585 mg, 4.75 mmol, 1.2 eq.) were added sequentially. The mixture was stirred at 24 °C for 3 h. The mixture was then poured into water (20 mL) and the mixture was stirred vigorously for 30 min. The aqueous phase was extracted with EtOAc (3 X 20 mL) and the combined organic layers were washed with H<sub>2</sub>O (20 mL) and brine and dried over Na<sub>2</sub>O<sub>4</sub>. The volatiles were removed under reduced pressure and the crude mixture was purified by column chromatography (cyclohexane:EtOAc, 98:2) to give the title compound (1.02 g, 3.39 mmol, 86%) as a colorless liquid.

<sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.52 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.31 (dd, *J* = 7.7, 1.6 Hz, 1H), 7.00 (t, *J* = 7.8 Hz, 1H), 5.19 (s, 2H), 3.89 (s, 3H), 1.23 (s, 9H).

<sup>13</sup>C NMR (126 MHz, CDCl<sub>3</sub>): δ (ppm) 178.5, 155.6, 133.7, 132.1, 129.1, 125.7, 117.6, 61.7, 61.6, 39.0, 27.4.

GC-MS (EI): Calcd for C<sub>13</sub>H<sub>17</sub><sup>79</sup>BrO<sub>3</sub> [M]<sup>+</sup>: 300, found 300

#### 3-Bromo-2-methoxybenzyl acetate (4.16c):

3-bromo-2-methoxybenzaldehyde (900 mg, 4.19 mmol, 1.0 eq.) was dissolved in MeOH (14 mL) and NaBH<sub>4</sub> (238 mg, 6.29 mmol, 1.5 eq.) was added portion wise at 0 °C. The reaction mixture was stirred at 24 °C for 3 h and quenched by the addition of H<sub>2</sub>O (5.0 mL). The aqueous phase was extracted with EtOAc and the combined organic layers were washed with H<sub>2</sub>O (15 mL), Brine (15 mL) and dried over Na<sub>2</sub>SO<sub>4</sub>. Afterwards the volatiles were removed under reduced pressure. The crude benzyl alcohol was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (8.0 mL) and pyridine (251 mg, 3.17 mmol, 0.80 eq.) and acetic anhydride (849 mg, 8.32 mmol, 2.1 eq.) were added sequentially. The mixture was stirred at 24 °C for 3 h. The mixture was then poured into water (20 mL) and the mixture was stirred vigorously for 30 min. The aqueous phase was extracted with EtOAc (3 X 20 mL) and the combined organic layers were washed with H<sub>2</sub>O (20 mL) and brine and dried over Na<sub>2</sub>O<sub>4</sub>. The volatiles were removed under reduced pressure

and the crude mixture was purified by column chromatography (cyclohexane:EtOAc, 95:10) to give the title compound (1.00 g, 3.86 mmol, 98%) as a colorless liquid.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.53 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.32 (dd, *J* = 7.7, 1.6 Hz, 1H), 7.00 (t, *J* = 7.8 Hz, 1H), 5.18 (s, 2H), 3.89 (s, 3H), 2.11 (s, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 170.9, 155.8, 134.1, 131.5, 129.6, 125.6, 117.6, 61.7, 21.2.

**GC-MS** (EI): Calcd for C<sub>10</sub>H<sub>11</sub><sup>79</sup>BrO<sub>3</sub> [M]<sup>+</sup>: 258, found 258

### 2-(3-Bromo-2-methoxybenzyl)isoindoline-1,3-dione (**4.16d**):

(3-bromo-2-methoxyphenyl)methanol (1.00 g, 4.61 mmol, 1.0 eq.) (prepared as above) was dissolved in CH<sub>2</sub>Cl<sub>2</sub> (45 mL) and PBr<sub>3</sub> (3.74 g, 13.8 mmol, 3.0 eq.) was added. The mixture was stirred at 24 °C for 3 h and then the volatiles were removed under reduced pressure. The crude mixture was redissolved in DMF (10 mL) and phthalimide potassium salt (613 mg, 3.31 mmol, 1.10 eq.) was added and the mixture was heated at 90 °C for 16 h. The volatiles were removed under reduced pressure and the residue dissolved in CH<sub>3</sub>Cl (15 mL) and filtered. The filtrate was washed with H<sub>2</sub>O (20 mL), brine (20 mL) and dried over Na<sub>2</sub>SO<sub>4</sub>. After removing the solvent under reduced pressure the crude product was passed through a short plug of silica to give the title compound (896 mg, 2.59 mmol, 86%) as a yellow oil.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.90 – 7.82 (m, 2H), 7.79 – 7.66 (m, 2H), 7.46 (dd, *J* = 8.0, 1.6 Hz, 1H), 7.20 (dd, *J* = 7.7, 1.5 Hz, 1H), 6.92 (t, *J* = 7.8 Hz, 1H), 4.94 (s, 2H), 3.98 (d, *J* = 0.7 Hz, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 168.1, 155.2, 134.2, 133.3, 132.2, 131.6, 128.6, 125.5, 123.5, 117.5, 61.2, 37.0.

**GC-MS** (EI): Calcd for C<sub>8</sub>H<sub>8</sub><sup>79</sup>BrO [M]<sup>+</sup>: 199, found 199

### 1-Bromo-2-methoxy-3-(1-methylcyclopropyl)benzene (**4.16e**):

To a solution of methyltriphenylphosphonium bromide (3.82 mg, 10.7 mmol, 2.30 eq.) in THF (28 mL) was added KO<sup>t</sup>Bu (1.18 g, 10.6 mmol, 2.3 eq.) at 0 °C. After stirring for 2 h at 0 °C 1-(3-bromo-2-methoxyphenyl)ethan-1-one (1.07 g, 4.65 mmol, 1.0 eq.) and the mixture was continued to stir at 24 °C for 6 h. The reaction was quenched by the addition of HCl (10 mL, 1M) and the aqueous phase was extracted with EtOAc (3 X 10 mL). The combined combined organic layers were washed with brine (2 X 10 mL) and dried over Na<sub>2</sub>SO<sub>4</sub>. After removing the volatiles under reduced pressure the crude was filtered over a plug of silica.

To dry CH<sub>2</sub>Cl<sub>2</sub> (5.0 mL) Et<sub>2</sub>Zn (6.18 g, 4.06 mmol, 2.0 eq.) was added under argon atmosphere. Then, TFA (463 mg, 4.06 mmol, 2.0 eq.) was added at 0 °C. After stirring for 20 min, a solution of CH<sub>2</sub>I<sub>2</sub> (2.18 g, 8.12 mmol, 4.0 eq.) in CH<sub>2</sub>Cl<sub>2</sub> (2.9 mL) was added. After stirring for additional 20 min a solution of the olefin obtained above in CH<sub>2</sub>Cl<sub>2</sub> (2.0 mL) was added slowly and the mixture stirred for 30 min at 24 °C. The reaction was quenched by the addition of HCl (5 mL, 0.1 M) and hexanes (10 mL) and the layers were separated. The aqueous layer was extracted with hexanes (3 X 10 mL) and the combined organic layers were washed with H<sub>2</sub>O (10 mL) and brine (10 mL). After drying over Na<sub>2</sub>SO<sub>4</sub>, the volatiles were removed under reduced pressure. Flash column chromatography (cyclohexane:EtOAc, 98:2) gave the title compound (434 mg, 1.80 mmol, 89%) as a colorless liquid.

**<sup>1</sup>H NMR** (500 MHz, CDCl<sub>3</sub>): δ (ppm) 7.40 (dt, *J* = 7.9, 1.2 Hz, 1H), 7.23 (dt, *J* = 7.7, 1.2 Hz, 1H), 6.89 (t, *J* = 7.8 Hz, 1H), 3.96 (s, 3H), 1.38 (s, 3H), 0.83 (t, *J* = 3.0 Hz, 2H), 0.72 (t, *J* = 3.2 Hz, 2H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 157.1, 142.0, 131.9, 130.2, 125.2, 117.9, 61.0, 26.4, 19.2, 14.1.

**GC-MS** (EI): Calcd for C<sub>11</sub>H<sub>13</sub><sup>79</sup>BrO [M]<sup>+</sup>: 240, found 240

### 1-(3-Bromo-2-methoxy-5-methylphenyl)propan-1-one (4.20a):

The title compound (2.30 g, 8.94 mmol, 91%) was prepared after a literature procedure. The analytical data is in full agreement with the reported one. <sup>[185]</sup>

**<sup>1</sup>H NMR** (400 MHz, CDCl<sub>3</sub>): δ (ppm) 7.49 – 7.47 (m, 1H), 7.26 – 7.24 (m, 1H), 3.82 (s, 3H), 2.96 (q, *J* = 7.3 Hz, 2H), 2.31 (d, *J* = 0.8 Hz, 3H), 1.17 (t, *J* = 7.3 Hz, 3H).

**<sup>13</sup>C NMR** (126 MHz, CDCl<sub>3</sub>): δ (ppm) 203.8, 153.3, 136.9, 135.7, 135.2, 129.1, 117.9, 62.6, 36.3, 20.6, 8.5.

# Marco Zuccarello

## Personal Information

Place of birth: Basel-Stadt, Switzerland

Current address: University of Basel, St. Johannis-Ring 19, 4056 Basel (work affiliation)  
Wasgenring 155, 4055 Basel (private affiliation)

Phone: +41 76 569 95 93

E-mail: marco.zuccarello@unibas.ch (work)  
zuccarello.marco@gmail.com (private)

OrcID: orcid.org/0000-0002-6081-8731

Nationality: Swiss/Italian

---

## Research Experience

Oct 2018 **Doctoral Study at University of Basel**  
Supervision by Prof. Dr. Olivier Baudoin ([olivier.baudoin@unibas.ch](mailto:olivier.baudoin@unibas.ch))  
Enantioselective Pd<sup>0</sup>-Catalyzed methylene C(sp<sup>3</sup>)-H activation reactions and mechanistic studies.

Feb – Sep 2018 **Master Thesis**  
Supervision by Prof. Dr. Olivier Baudoin  
Dr. Romain Melot ([melot@kofo.mpg.de](mailto:melot@kofo.mpg.de))  
Title: Enantioselective Synthesis of Substituted Indanes via Pd(0)-Catalyzed Methylene C(sp<sup>3</sup>)-H Bond Activation

Aug – Sep 2017 **Research Project II**  
Supervision by Prof. Dr. Olivier Baudoin  
Title: Towards a Novel Family of Bifunctional NHC Ligands for Enantioselective C-H Activation

Aug – Sep 2016 **Research Project I**  
Supervision by Prof. Dr. Christof Sparr ([christof.sparr@unibas.ch](mailto:christof.sparr@unibas.ch))  
Title: Synthesis of Electron-Deficient Tetra-Ketones for Atroposelective Arene-Forming Aldol Condensation

## Education

Oct 2018 – **Ph.D. studies**  
University of Basel, Switzerland  
Advisor: Prof. Dr. O. Baudoin

Sep 2017 – Aug 2018 **M.Sc. in Chemistry**  
University of Basel Chemistry, Switzerland  
Supervisors: Dr. R. Melot and Prof. Dr. O. Baudoin  
Final grade 5.7 out of 6

Feb 2014 – Jul 2017      **B.Sc in Chemistry**  
University of Basel, Switzerland  
Final grade 5.2 out of 6

### **Employment history**

Oct 2018 –                      **University of Basel**  
Doctoral candidate  
Advisor: Prof. Dr. O. Baudoin

### **Institutional responsibilities**

Oct 2018 –                      Floor evacuation responsible  
Dec 2016 – Oct 2018      Vice president of the “Verband Basler Chemiestudierender (VBC)”

### **Supervision of Junior Researchers**

Feb – Apr 2022              **Research Mentor**  
Domenic Kronenberg (internship on M.Sc. level)  
Sep – Dec 2020              **Research Mentor**  
Géraldine Kiechler (internship on M.Sc. level)  
Aug – Nov 2019              **Research Mentor**  
Alex Cavadini (internship on M.Sc. level)  
May – June 2019              **Research Mentor**  
Andreas Ostertag (internship on B.Sc. level)

### **Teaching**

Feb – June 2021              **Supervision of Advanced Chemistry Practical Course**  
Laboratory course for 6<sup>th</sup> semester Bachelor students  
Feb – June 2020              **Supervision of Advanced Chemistry Practical Course**  
Laboratory course for 6<sup>th</sup> semester Bachelor students  
Feb – June 2019              **Supervision of Advanced Chemistry Practical Course**  
Laboratory course for 6<sup>th</sup> semester Bachelor students

### **Memberships in Panels**

Jan 2020 – Jan 2021      Co-Author of the “Swiss Science Concentrates” published in *Chimia*

### **Active Memberships**

Oct 2018                      Member of the Swiss Chemical Society

## Personal Skills

### Languages:

**Italian** (Mother tongue)

**Swissgerman** (fluent)

**Spanish** (basic level)

**German** (fluent)

**English** (fluent)

**French** (basic level)

### Instruments:

- Operation and maintenance of high-pressure liquid chromatography (HPLC) systems on analytical and preparative scale.
- Operation of GC-MS, TLC-MS, Glovebox

## Publications in Peer-Reviewed Scientific Journals

Melot, R.<sup>†</sup>; **Zuccarello, M.**<sup>†</sup>; Cavalli, D.; Niggli, N.; Baudoin, O. “Pd<sup>0</sup>-catalyzed Enantioselective Intramolecular Arylation of Enantiotopic Secondary C–H Bonds”, *Angew. Chem. Int. Ed.* **2021**, 60, 7245–7250. († denotes equal contribution). [Link](#)

## Contribution to Conferences

- 25<sup>th</sup> Aug. 2020 Melot, R.<sup>†</sup>; **Zuccarello, M.**<sup>†</sup>; Cavalli, D.; Niggli, N.; Baudoin, O. “Pd<sup>0</sup>-catalyzed Enantioselective Intramolecular Arylation of Enantiotopic Secondary C–H Bonds” *Poster presentation*, SCS Fall Meeting 2020 (online conference), Bern, Switzerland, 2020.
- 30<sup>th</sup> Oct. 2020 Melot, R.<sup>†</sup>; **Zuccarello, M.**<sup>†</sup>; Cavalli, D.; Niggli, N.; Baudoin, O. “Pd<sup>0</sup>-catalyzed Enantioselective Intramolecular Arylation of Enantiotopic Secondary C–H Bonds” *Poster presentation*, SCS 3<sup>rd</sup> Swiss Industrial Chemistry Symposium (online conference), Switzerland, 2020.
- 10<sup>th</sup> Sep. 2021 Melot, R.<sup>†</sup>; **Zuccarello, M.**<sup>†</sup>; Cavalli, D.; Niggli, N.; Baudoin, O. “Pd<sup>0</sup>-catalyzed Enantioselective Intramolecular Arylation of Enantiotopic Secondary C–H Bonds” *Poster presentation*, SCS Fall Meeting 2021 (online conference), Switzerland, 2021.
- 3-8<sup>th</sup> Jul. 2022 Melot, R.<sup>†</sup>; **Zuccarello, M.**<sup>†</sup>; Cavalli, D.; Niggli, N.; Baudoin, O. “Pd<sup>0</sup>-catalyzed Enantioselective Intramolecular Arylation of Enantiotopic Secondary C–H Bonds” *Poster presentation*, 17<sup>th</sup> Belgian Organic Synthesis Symposium (BOSS XVII), Namur, Belgium, 2022.
